Package ‘mxnet’

April 19, 2021

Type Package

Title MXNet: A Flexible and Efficient Machine Learning Library for Heterogeneous Distributed Systems

Version 1.8.0

Date 2017-06-27

Author Tianqi Chen, Qiang Kou, Tong He, Anirudh Acharya <https://github.com/anirudhacharya>

Maintainer Qiang Kou <qkou@qkou.info>

Repository apache/incubator-mxnet

Description MXNet is a deep learning framework designed for both efficiency and flexibility. It allows you to mix the flavours of deep learning programs together to maximize the efficiency and your productivity.

License Apache License (== 2.0)

URL https://github.com/apache/incubator-mxnet/tree/master/R-package

BugReports https://github.com/apache/incubator-mxnet/issues

Imports methods,
Rcpp (>= 0.12.1),
DiagrammeR (>= 0.9.0),
visNetwork (>= 1.0.3),
data.table,
jsonlite,
magrittr,
stringr

Suggests testthat,
mlbench,
knitr,
rmarkdown,
imager,
covr

Depends R (>= 3.4.4)

LinkingTo Rcpp

VignetteBuilder knitr
RoxygenNote 7.1.1
Encoding UTF-8

R topics documented:

**arguments**

*Get the arguments of symbol.*

**Description**

Get the arguments of symbol.

**Usage**

`arguments(x)`

**Arguments**

- `x` The input symbol
### as.array.MXNDArray

**Description**

as.array operator overload of mx.ndarray

**Usage**

```r
## S3 method for class 'MXNDArray'
as.array(nd)
```

**Arguments**

- **nd** The mx.ndarray

---

### as.matrix.MXNDArray

**Description**

as.matrix operator overload of mx.ndarray

**Usage**

```r
## S3 method for class 'MXNDArray'
as.matrix(nd)
```

**Arguments**

- **nd** The mx.ndarray

---

### children

**Description**

Gets a new grouped symbol whose output contains inputs to output nodes of the original symbol.

**Usage**

```r
children(x)
```

**Arguments**

- **x** The input symbol
**ctx**

*Get the context of mx.ndarray*

**Description**

Get the context of mx.ndarray

**Usage**

```python
ctx(nd)
```

**Arguments**

- `nd`: The mx.ndarray

**dim.MXNDArray**

*Dimension operator overload of mx.ndarray*

**Description**

Dimension operator overload of mx.ndarray

**Usage**

```r
## S3 method for class 'MXNDArray'
dim(nd)
```

**Arguments**

- `nd`: The mx.ndarray

**graph.viz**

*Convert symbol to Graphviz or visNetwork visualisation.*

**Description**

Convert symbol to Graphviz or visNetwork visualisation.
Usage

```r
graph.viz(
    symbol,
    shape = NULL,
    direction = "TD",
    type = "graph",
    graph.width.px = NULL,
    graph.height.px = NULL
)
```

Arguments

- `symbol`: a string representing the symbol of a model.
- `shape`: a numeric representing the input dimensions to the symbol.
- `direction`: a string representing the direction of the graph, either TD or LR.
- `type`: a string representing the rendering engine of the graph, either graph or vis.
- `graph.width.px`: a numeric representing the size (width) of the graph. In pixels
- `graph.height.px`: a numeric representing the size (height) of the graph. In pixels

Value

a graph object ready to be displayed with the `print` function.

Description

Convert images into image recordio format

Usage

```r
im2rec(
    image_lst,
    root,
    output_rec,
    label_width = 1L,
    pack_label = 0L,
    new_size = -1L,
    nsplit = 1L,
    partid = 0L,
    center_crop = 0L,
    quality = 95L,
    color_mode = 1L,
)```
unchanged = 0L,
inter_method = 1L,
encoding = "jpg"
)

Arguments

image_lst  The image lst file
root      The root folder for image files
output_rec The output rec file
label_width The label width in the list file. Default is 1.
pack_label Whether to also pack multi dimensional label in the record file. Default is 0.
new_size   The shorter edge of image will be resized to the newsize. Original images will
            be packed by default.
nsplit     It is used for part generation, logically split the image.lst to NSPLIT parts by
            position. Default is 1.
partid     It is used for part generation, pack the images from the specific part in image.lst.
            Default is 0.
center_crop Whether to crop the center image to make it square. Default is 0.
quality    JPEG quality for encoding (1-100, default: 95) or PNG compression for encoding
            (1-9, default: 3).
color_mode Force color (1), gray image (0) or keep source unchanged (-1). Default is 1.
unchanged  Keep the original image encoding, size and color. If set to 1, it will ignore the
            others parameters.
inter_method NN(0), BILINEAR(1), CUBIC(2), AREA(3), LANCZOS4(4), AUTO(9), RAND(10).
            Default is 1.
encoding   The encoding type for images. It can be `.jpg` or `.png`. Default is `.jpg`.

internals  Get a symbol that contains all the internals

Description

Get a symbol that contains all the internals

Usage

internals(x)

Arguments

x  The input symbol
is.mx.context

Description
Check if the type is mxnet context.

Usage
is.mx.context(x)

Value
Logical indicator

is.mx.dataiter

Description
Judge if an object is mx.dataiter

Usage
is.mx.dataiter(x)

Value
Logical indicator

is.mx.ndarray

Description
Check if src.array is mx.ndarray

Usage
is.mx.ndarray(src.array)

Value
Logical indicator
Examples

```
mat = mx.nd.array(1:10)
is.mx.ndarray(mat)
mat2 = 1:10
is.mx.ndarray(mat2)
```

---

**is.mx.symbol**

*Judge if an object is mx.symbol*

**Description**

Judge if an object is mx.symbol

**Usage**

```
is.mx.symbol(x)
```

**Value**

Logical indicator

---

**is.serialized**

*Check if the model has been serialized into RData-compatible format.*

**Description**

Check if the model has been serialized into RData-compatible format.

**Usage**

```
is.serialized(model)
```

**Value**

Logical indicator
### length.MXNDArray

**Description**

Length operator overload of mx.ndarray

**Usage**

````
## S3 method for class 'MXNDArray'
length(nd)
```

**Arguments**

- `nd` The mx.ndarray

---

### mx.apply

**Description**

Apply symbol to the inputs.

**Usage**

````
mx.apply(x, ...)
```

**Arguments**

- `x` The symbol to be applied
- `kwargs` The keyword arguments to the symbol
**mx.callback.early.stop**

*Early stop with different conditions*

**Description**

Early stopping applying different conditions: hard thresholds or epochs number from the best score. Tested with "epoch.end.callback" function.

**Usage**

```r
mx.callback.early.stop(
  train.metric = NULL,
  eval.metric = NULL,
  bad.steps = NULL,
  maximize = FALSE,
  verbose = FALSE
)
```

**Arguments**

- `train.metric` Numeric. Hard threshold for the metric of the training data set (optional)
- `eval.metric` Numeric. Hard threshold for the metric of the evaluating data set (if set, optional)
- `bad.steps` Integer. How much epochs should gone from the best score? Use this option with evaluation data set
- `maximize` Logical. Do your model use maximizing or minimizing optimization?
- `verbose` Logical

**mx.callback.log.speedometer**

*Calculate the training speed*

**Description**

Calculate the training speed

**Usage**

```r
mx.callback.log.speedometer(batch.size, frequency = 50)
```

**Arguments**

- `frequency` The frequency of the training speed update
- `batch_size` The batch size
mx.callback.log.train.metric

*Log training metric each period*

**Description**

Log training metric each period

**Usage**

mx.callback.log.train.metric(period, logger = NULL)

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>period</td>
<td>The number of batch to log the training evaluation metric</td>
</tr>
<tr>
<td>logger</td>
<td>The logger class</td>
</tr>
</tbody>
</table>

mx.callback.save.checkpoint

*Save checkpoint to files each period iteration.*

**Description**

Save checkpoint to files each period iteration.

**Usage**

mx.callback.save.checkpoint(prefix, period = 1)

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>prefix</td>
<td>The prefix of the model checkpoint.</td>
</tr>
</tbody>
</table>
mx.cpu

Create a mxnet CPU context.

Description

Create a mxnet CPU context.

Arguments

dev.id  optional, default=0 The device ID, this is meaningless for CPU, included for interface compatiblity.

Value

The CPU context.

mx.ctx.default

Set/Get default context for array creation.

Description

Set/Get default context for array creation.

Usage

mx.ctx.default(new = NULL)

Arguments

new  optional takes mx.cpu() or mx.gpu(id), new default ctx.

Value

The default context.

mx.exec.backward

Perform an backward on the executors This function will MUTATE the state of exec

Description

Perform an backward on the executors This function will MUTATE the state of exec

Usage

mx.exec.backward(exec, ...)

mx.exec.forward

Perform an forward on the executors This function will MUTATE the state of exec

Description

Perform an forward on the executors This function will MUTATE the state of exec

Usage

mx.exec.forward(exec, is.train = TRUE)

mx.exec.update.arg.arrays

Update the executors with new arrays This function will MUTATE the state of exec

Description

Update the executors with new arrays This function will MUTATE the state of exec

Usage

mx.exec.update.arg.arrays(
  exec,
  arg.arrays,
  match.name = FALSE,
  skip.null = FALSE
)

mx.exec.update.aux.arrays

Update the executors with new arrays This function will MUTATE the state of exec

Description

Update the executors with new arrays This function will MUTATE the state of exec
Usage

```r
mx.exec.update.grad.arrays(
  exec,
  arg.arrays,
  match.name = FALSE,
  skip.null = FALSE
)
```

Description

Update the executors with new arrays. This function will MUTATE the state of exec.

Usage

```r
mx.exec.update.grad.arrays(
  exec,
  arg.arrays,
  match.name = FALSE,
  skip.null = FALSE
)
```

mx.gpu

Create a mxnet GPU context.

Description

Create a mxnet GPU context.

Arguments

dev.id optional, default=0 The GPU device ID, starts from 0.

Value

The GPU context.
mx.infer.rnn

**Inference of RNN model**

**Description**
Inference of RNN model

**Usage**
```python
mx.infer.rnn(infer.data, model, ctx = mx.cpu())
```

**Arguments**
- `infer.data`: DataIter
- `model`: Model used for inference
- `ctx`

mx.infer.rnn.one

**Inference for one-to-one fusedRNN (CUDA) models**

**Description**
Inference for one-to-one fusedRNN (CUDA) models

**Usage**
```python
mx.infer.rnn.one(
    infer.data,
    symbol,
    arg.params,
    aux.params,
    input.params = NULL,
    ctx = mx.cpu()
)
```

**Arguments**
- `infer.data`: Data iterator created by mx.io.bucket.iter
- `symbol`: Symbol used for inference
- `ctx`
mx.infer.rnn.one.unroll

Inference for one-to-one unroll models

Description

Inference for one-to-one unroll models

Usage

```r
mx.infer.rnn.one.unroll(
  infer.data,
  symbol,
  num_hidden,
  arg.params,
  aux.params,
  init_states = NULL,
  ctx = mx.cpu()
)
```

Arguments

- `infer.data` : NDArray
- `symbol` : Model used for inference
- `num_hidden` :
- `ctx` :

mx.init.create

Create initialization of argument like arg.array

Description

Create initialization of argument like arg.array

Usage

```r
mx.init.create(initializer, shape.array, ctx = NULL, skip.unknown = TRUE)
```

Arguments

- `initializer` : The initializer.
- `shape.array` : A named list that represents the shape of the weights
- `ctx` : `mx.context` The context of the weights
- `skip.unknown` : Whether skip the unknown weight types
mx.init.internal.default

*Internal default value initialization scheme.*

**Description**

Internal default value initialization scheme.

**Usage**

```r
mx.init.internal.default(name, shape, ctx, allow.unknown = FALSE)
```

**Arguments**

- `name`: the name of the variable.
- `shape`: the shape of the array to be generated.

---

mx.init.normal

*Create a initializer that initialize the weight with normal(0, sd)*

**Description**

Create a initializer that initialize the weight with normal(0, sd)

**Usage**

```r
mx.init.normal(sd)
```

**Arguments**

- `sd`: The standard deviation of normal distribution

---

mx.init.uniform

*Create a initializer that initialize the weight with uniform [-scale, scale]*

**Description**

Create a initializer that initialize the weight with uniform [-scale, scale]

**Usage**

```r
mx.init.uniform(scale)
```

**Arguments**

- `scale`: The scale of uniform distribution
### mx.init.Xavier

**Xavier initializer**

<table>
<thead>
<tr>
<th>mx.init.Xavier</th>
</tr>
</thead>
</table>

**Description**

Create a initializer which initialize weight with Xavier or similar initialization scheme.

**Usage**

```r
mx.init.Xavier(rnd_type = "uniform", factor_type = "avg", magnitude = 3)
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rnd_type</td>
<td>A string of character indicating the type of distribution from which the weights are initialized.</td>
</tr>
<tr>
<td>factor_type</td>
<td>A string of character.</td>
</tr>
<tr>
<td>magnitude</td>
<td>A numeric number indicating the scale of random number range.</td>
</tr>
</tbody>
</table>

### mx.io.arrayiter

Create MXDataIter compatible iterator from R’s array

<table>
<thead>
<tr>
<th>mx.io.arrayiter</th>
</tr>
</thead>
</table>

**Description**

Create MXDataIter compatible iterator from R’s array

**Usage**

```r
mx.io.arrayiter(data, label, batch.size = 128, shuffle = FALSE)
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>The data array.</td>
</tr>
<tr>
<td>label</td>
<td>The label array.</td>
</tr>
<tr>
<td>batch.size</td>
<td>The batch size used to pack the array.</td>
</tr>
<tr>
<td>shuffle</td>
<td>Whether shuffle the data</td>
</tr>
</tbody>
</table>
mx.io.bucket.iter

Create Bucket Iter

Description

Create Bucket Iter

Usage

mx.io.bucket.iter(
    buckets,
    batch.size,
    data.mask.element = 0,
    shuffle = FALSE,
    seed = 123
)

Arguments

buckets The data array.
batch.size The batch size used to pack the array.
data.mask.element The element to mask
shuffle Whether shuffle the data
seed The random seed

mx.io.CSVIter

Returns the CSV file iterator.

Description

In this function, the `data_shape` parameter is used to set the shape of each line of the input data. If a row in an input file is ‘1,2,3,4,5,6” and ‘data_shape’ is (3,2), that row will be reshaped, yielding the array [[1,2],[3,4],[5,6]] of shape (3,2).

Usage

mx.io.CSVIter(...)
**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data.csv</td>
<td>string, required</td>
<td>The input CSV file or a directory path.</td>
</tr>
<tr>
<td>data.shape</td>
<td>Shape(tuple), required</td>
<td>The shape of one example.</td>
</tr>
<tr>
<td>label.csv</td>
<td>string, optional, default='NULL'</td>
<td>The input CSV file or a directory path. If NULL, all labels will be returned as 0.</td>
</tr>
<tr>
<td>label.shape</td>
<td>Shape(tuple), optional, default=[1]</td>
<td>The shape of one label.</td>
</tr>
<tr>
<td>batch.size</td>
<td>int (non-negative), required</td>
<td>Batch size.</td>
</tr>
<tr>
<td>round.batch</td>
<td>boolean, optional, default=1</td>
<td>Whether to use round robin to handle overflow batch or not.</td>
</tr>
<tr>
<td>prefetch.buffer</td>
<td>long (non-negative), optional, default=4</td>
<td>Maximum number of batches to prefetch.</td>
</tr>
<tr>
<td>ctx</td>
<td>'cpu', 'gpu', optional, default='gpu'</td>
<td>Context data loader optimized for.</td>
</tr>
<tr>
<td>dtype</td>
<td>None, 'bfloat16', 'float16', 'float32', 'float64', 'int32', 'int64', 'int8', 'uint8', optional, default='None'</td>
<td>Output data type. “None” means no change.</td>
</tr>
</tbody>
</table>

**Details**

By default, the `CSVIter` has `round_batch` parameter set to “True”. So, if `batch_size` is 3 and there are 4 total rows in CSV file, 2 more examples are consumed at the first round. If `reset` function is called after first round, the call is ignored and remaining examples are returned in the second round.

If one wants all the instances in the second round after calling `reset`, make sure to set `round_batch` to False.

If “data.csv = ’data/‘” is set, then all the files in this directory will be read.

“reset()” is expected to be called only after a complete pass of data.

By default, the CSVIter parses all entries in the data file as float32 data type, if `dtype` argument is set to be ‘int32’ or ‘int64’ then CSVIter will parse all entries in the file as int32 or int64 data type accordingly.

**Examples:**

```python
// Contents of CSV file “data/data.csv“: 1,2,3 2,3,4 3,4,5 4,5,6
// Creates a ‘CSVIter’ with ‘batch_size’=2 and default ‘round_batch’=True. CSVIter = mx.io.CSVIter(data_csv = ’data/data.csv’, data_shape = (3,), batch_size = 2)
// Two batches read from the above iterator are as follows: [[1. 2. 3.]. [2. 3. 4.]. [3. 4. 5.]. [4. 5. 6.].]

// Creates a ‘CSVIter’ with default ‘round_batch’ set to True. CSVIter = mx.io.CSVIter(data_csv = ’data/data.csv’, data_shape = (3,), batch_size = 3)
// Two batches read from the above iterator in the first pass are as follows: [[1. 2. 3.]. [2. 3. 4.]. [3. 4. 5.].]
[[4. 5. 6.]. [1. 2. 3.]. [2. 3. 4.].]

// Now, ‘reset’ method is called. CSVIter.reset()
// Batch read from the above iterator in the second pass is as follows: [[3. 4. 5.]. [4. 5. 6.]. [1. 2. 3.].]```
// Creates a 'CSVIter' with 'round_batch'=False. CSVIter = mx.io.CSVIter(data_csv = 'data/data.csv',
data_shape = (3,), batch_size = 3, round_batch=False)

// Contents of two batches read from the above iterator in both passes, after calling // 'reset' method before second pass, is as follows: [[1. 2. 3.] [2. 3. 4.] [3. 4. 5.]]
[[4. 5. 6.] [2. 3. 4.] [3. 4. 5.]]

// Creates a 'CSVIter' with 'dtype'='int32' CSVIter = mx.io.CSVIter(data_csv = 'data/data.csv',
data_shape = (3,), batch_size = 3, round_batch=False, dtype='int32')

// Contents of two batches read from the above iterator in both passes, after calling // 'reset' method before second pass, is as follows: [[1 2 3] [2 3 4] [3 4 5]]
[[4 5 6] [2 3 4] [3 4 5]]
Defined in src/io/iter_csv.cc:L308

**Value**

iter The result mx.dataiter

---

**mx.io.extract**

*Extract a certain field from DataIter.*

---

**Description**

Extract a certain field from DataIter.

**Usage**

mx.io.extract(iter, field)

---

**mx.io.ImageDetRecordIter**

*Create iterator for image detection dataset packed in recordio.*

---

**Description**

Create iterator for image detection dataset packed in recordio.

**Usage**

mx.io.ImageDetRecordIter(...)
Arguments

- **path.imglist**: string, optional, default=`` Dataset Param: Path to image list.
- **path.imgrec**: string, optional, default=`` Dataset Param: Path to image record file.
- **aug.seq**: string, optional, default='det_aug_default' Augmentation Param: the augmenter names to represent sequence of augmenters to be applied, seperated by comma. Additional keyword parameters will be seen by these augmenters. Make sure you don’t use normal augmenters for detection tasks.
- **label.width**: int, optional, default='-1' Dataset Param: How many labels for an image, -1 for variable label size.
- **preprocess.threads**: int, optional, default='4' Backend Param: Number of thread to do preprocessing.
- **verbose**: boolean, optional, default=1 Auxiliary Param: Whether to output parser information.
- **num.parts**: int, optional, default='1' partition the data into multiple parts
- **part.index**: int, optional, default='0' the index of the part will read
- **shuffle.chunk.size**: long (non-negative), optional, default=0 the size(MB) of the shuffle chunk, used with shuffle=True, it can enable global shuffling
- **shuffle.chunk.seed**: int, optional, default='0' the seed for chunk shuffling
- **label.pad.width**: int, optional, default='0' pad output label width if set larger than 0, -1 for auto estimate
- **label.pad.value**: float, optional, default=-1 label padding value if enabled
- **shuffle**: boolean, optional, default=0 Augmentation Param: Whether to shuffle data.
- **seed**: int, optional, default='0' Augmentation Param: Random Seed.
- **batch.size**: int (non-negative), required Batch size.
- **round.batch**: boolean, optional, default=1 Whether to use round robin to handle overflow batch or not.
- **prefetch.buffer**: long (non-negative), optional, default=4 Maximum number of batches to prefetch.
- **ctx**: 'cpu', 'gpu',optional, default='gpu' Context data loader optimized for.
- **dtype**: None, 'bfloat16', 'float16', 'float32', 'float64', 'int32', 'int64', 'int8', 'uint8',optional, default=’None’ Output data type. “None“ means no change.
- **resize**: int, optional, default='-1' Augmentation Param: scale shorter edge to size before applying other augmentations, -1 to disable.
- **rand.crop.prob**: float, optional, default=0 Augmentation Param: Probability of random cropping, <= 0 to disable
- **min.crop.scales**: tuple of <float>, optional, default=[0] Augmentation Param: Min crop scales.
max.crop.scales

min.crop.aspect.ratios

max.crop.aspect.ratios

min.crop.overlaps
tuple of <float>, optional, default=[0] Augmentation Param: Minimum crop IOU between crop_box and ground-truths.

max.crop.overlaps

min.crop.sample.coverages
tuple of <float>, optional, default=[0] Augmentation Param: Minimum ratio of intersect/crop_area between crop box and ground-truths.

max.crop.sample.coverages

min.crop.object.coverages
tuple of <float>, optional, default=[0] Augmentation Param: Minimum ratio of intersect/gt_area between crop box and ground-truths.

max.crop.object.coverages

num.crop.sampler
int, optional, default='1' Augmentation Param: Number of crop samplers.

crop.emit.mode
'center', 'overlap', optional, default='center' Augmentation Param: Emission mode for invalid ground-truths after crop. center: emit if centroid of object is out of crop region; overlap: emit if overlap is less than emit_overlap_thresh.

emit.overlap.thresh
float, optional, default=0.300000012 Augmentation Param: Emit overlap thresh for emit mode overlap only.

max.crop.trials
Shape(tuple), optional, default=[25] Augmentation Param: Skip cropping if fail crop trail count exceeds this number.

rand.pad.prob
float, optional, default=0 Augmentation Param: Probability for random padding.

max.pad.scale
float, optional, default=1 Augmentation Param: Maximum padding scale.

max.random.hue
int, optional, default='0' Augmentation Param: Maximum random value of H channel in HSL color space.

random.hue.prob
float, optional, default=0 Augmentation Param: Probability to apply random hue.
max.random.saturation
int, optional, default='0' Augmentation Param: Maximum random value of S channel in HSL color space.

random.saturation.prob
float, optional, default=0 Augmentation Param: Probability to apply random saturation.

max.random.illumination
int, optional, default='0' Augmentation Param: Maximum random value of L channel in HSL color space.

random.illumination.prob
float, optional, default=0 Augmentation Param: Probability to apply random illumination.

max.random.contrast
float, optional, default=0 Augmentation Param: Maximum random value of delta contrast.

random.contrast.prob
float, optional, default=0 Augmentation Param: Probability to apply random contrast.

rand.mirror.prob
float, optional, default=0 Augmentation Param: Probability to apply horizontal flip aka. mirror.

fill.value
int, optional, default='127' Augmentation Param: Filled color value while padding.

inter.method
int, optional, default='1' Augmentation Param: 0-NN 1-bilinear 2-cubic 3-area 4-lanczos4 9-auto 10-rand.

data.shape
Shape(tuple), required Dataset Param: Shape of each instance generated by the DataIter.

resize.mode
'fit', 'force', 'shrink', optional, default='force' Augmentation Param: How image data fit in data_shape. force: force reshape to data_shape regardless of aspect ratio; shrink: ensure each side fit in data_shape, preserve aspect ratio; fit: fit image to data_shape, preserve ratio, will upscale if applicable.

mean.img
string, optional, default="" Augmentation Param: Mean Image to be subtracted.

mean.r
float, optional, default=0 Augmentation Param: Mean value on R channel.

mean.g
float, optional, default=0 Augmentation Param: Mean value on G channel.

mean.b
float, optional, default=0 Augmentation Param: Mean value on B channel.

mean.a
float, optional, default=0 Augmentation Param: Mean value on Alpha channel.

std.r
float, optional, default=0 Augmentation Param: Standard deviation on R channel.

std.g
float, optional, default=0 Augmentation Param: Standard deviation on G channel.

std.b
float, optional, default=0 Augmentation Param: Standard deviation on B channel.

std.a
float, optional, default=0 Augmentation Param: Standard deviation on Alpha channel.

scale
float, optional, default=1 Augmentation Param: Scale in color space.
Value

iter The result mx.dataiter

mx.io.ImageRecordInt8Iter

Iterating on image RecordIO files

Description

.. note:: “ImageRecordInt8Iter” is deprecated. Use ImageRecordIter(dtype='int8') instead.

Usage

mx.io.ImageRecordInt8Iter(...)

Arguments

*path.imglist* string, optional, default=’Path to the image list (.lst) file. Generally created with tools/im2rec.py. Format (Tab separated): <index of record> <one or more labels> <relative path from root folder>.

*path.imgrec* string, optional, default=’Path to the image RecordIO (.rec) file or a directory path. Created with tools/im2rec.py.

*path.imgidx* string, optional, default=’Path to the image RecordIO index (.idx) file. Created with tools/im2rec.py.

*aug.seq* string, optional, default=’aug_default’ The augmenter names to represent sequence of augmenters to be applied, separated by comma. Additional keyword parameters will be seen by these augmenters.

*label.width* int, optional, default=’1’ The number of labels per image.

*preprocess.threads* int, optional, default=’4’ The number of threads to do preprocessing.

*verbose* boolean, optional, default=1 If or not output verbose information.

*num.parts* int, optional, default=’1’ Virtually partition the data into these many parts.

*part.index* int, optional, default=’0’ The *i*-th virtual partition to be read.

*device.id* int, optional, default=’0’ The device id used to create context for internal NDArray. Setting device_id to -1 will create Context::CPU(0). Setting device_id to a valid positive device id will create Context::CPUPinned(device_id). Default is 0.

*shuffle.chunk.size* long (non-negative), optional, default=0 The data shuffle buffer size in MB. Only valid if shuffle is true.

*shuffle.chunk.seed* int, optional, default=’0’ The random seed for shuffling

*seed.aug* int or None, optional, default=’None’ Random seed for augmentations.
shuffle boolean, optional, default=0 Whether to shuffle data randomly or not.
seed int, optional, default=’0’ The random seed.
batch.size int (non-negative), required Batch size.
round.batch boolean, optional, default=1 Whether to use round robin to handle overflow batch or not.
prefetch.buffer long (non-negative), optional, default=4 Maximum number of batches to prefetch.
ctx ’cpu’, ’gpu’,optional, default=’gpu’ Context data loader optimized for.
resize int, optional, default=’-1’ Down scale the shorter edge to a new size before applying other augmentations.
rand.crop boolean, optional, default=0 If or not randomly crop the image
random.resized.crop boolean, optional, default=0 If or not perform random resized cropping on the image, as a standard preprocessing for resnet training on ImageNet data.
max.rotate.angle int, optional, default=’0’ Rotate by a random degree in “[-v, v]”
max.aspect.ratio float, optional, default=0 Change the aspect (namely width/height) to a random value. If min_aspect_ratio is None then the aspect ratio ins sampled from [1 - max_aspect_ratio, 1 + max_aspect_ratio], else it is in “[min_aspect_ratio, max_aspect_ratio]”
min.aspect.ratio float or None, optional, default=None Change the aspect (namely width/height) to a random value in “[min_aspect_ratio, max_aspect_ratio]”
max.shear.ratio float, optional, default=0 Apply a shear transformation (namely “(x,y)->(x+my,y)”) with “m” randomly chose from “[-max_shear_ratio, max_shear_ratio]”
max.crop.size int, optional, default=’-1’ Crop both width and height into a random size in “[min_crop_size, max_crop_size].”Ignored if “random_resized_crop” is True.
min.crop.size int, optional, default=’-1’ Crop both width and height into a random size in “[min_crop_size, max_crop_size].”Ignored if “random_resized_crop” is True.
max.random.scale float, optional, default=1 Resize into “[width*s, height*s]” with ‘s’ randomly chosen from “[min_random_scale, max_random_scale]”. Ignored if “random_resized_crop” is True.
min.random.scale float, optional, default=1 Resize into “[width*s, height*s]” with ‘s’ randomly chosen from “[min_random_scale, max_random_scale]”Ignored if “random_resized_crop” is True.
max.random.area float, optional, default=1 Change the area (namely width * height) to a random value in “[min_random_area, max_random_area]”. Ignored if “random_resized_crop” is False.
min.random.area
float, optional, default=1 Change the area (namely width * height) to a random value in "[min_random_area, max_random_area]". Ignored if "random_resized_crop" is False.

max.img.size
float, optional, default=1e+10 Set the maximal width and height after all resize and rotate argumentation are applied

min.img.size
float, optional, default=0 Set the minimal width and height after all resize and rotate argumentation are applied

brightness
float, optional, default=0 Add a random value in "[-brightness, brightness]" to the brightness of image.

contrast
float, optional, default=0 Add a random value in "[-contrast, contrast]" to the contrast of image.

saturation
float, optional, default=0 Add a random value in "[-saturation, saturation]" to the saturation of image.

pca.noise
float, optional, default=0 Add PCA based noise to the image.

random.h
int, optional, default='0' Add a random value in "[-random_h, random_h]" to the H channel in HSL color space.

random.s
int, optional, default='0' Add a random value in "[-random_s, random_s]" to the S channel in HSL color space.

random.l
int, optional, default='0' Add a random value in "[-random_l, random_l]" to the L channel in HSL color space.

rotate
int, optional, default='1' Rotate by an angle. If set, it overwrites the “max_rotate_angle” option.

fill.value
int, optional, default='255' Set the padding pixels value to “fill_value“.

data.shape
Shape(tuple), required The shape of a output image.

inter.method
int, optional, default='1' The interpolation method: 0-NN 1-bilinear 2-cubic 3-area 4-lanczos4 9-auto 10-rand.

pad
int, optional, default='0' Change size from "[width, height]" into "[pad + width + pad, pad + height + pad]" by padding pixes

Details
This iterator is identical to “ImageRecordIter” except for using “int8” as the data type instead of “float”.

Defined in src/io/iter_image_recordio_2.cc:L941

max.crop.size int, optional, default=-1’ Crop both width and height into a random size in
“[min_crop_size, max_crop_size].”Ignored if “random_resized_crop” is True.
min.crop.size int, optional, default=-1’ Crop both width and height into a random size in
“[min_crop_size, max_crop_size].”Ignored if “random_resized_crop” is True.
max.random.scale float, optional, default=1 Resize into “[width*s, height*s]” with “s” randomly
chosen from “[min_random_scale, max_random_scale]”. Ignored if “random_resized_crop”
is True.
min.random.scale float, optional, default=1 Resize into “[width*s, height*s]” with “s” randomly
chosen from “[min_random_scale, max_random_scale]”Ignored if “random_resized_crop”
is True.
max.random.area float, optional, default=1 Change the area (namely width * height) to a random
value in “[min_random_area, max_random_area]”. Ignored if “random_resized_crop”
is False.
min.random.area float, optional, default=1 Change the area (namely width * height) to a random
value in “[min_random_area, max_random_area]”. Ignored if “random_resized_crop”
is False.
max.img.size float, optional, default=1e+10 Set the maximal width and height after all resize
and rotate argumentation are applied
min.img.size float, optional, default=0 Set the minimal width and height after all resize and
rotate argumentation are applied
brightness float, optional, default=0 Add a random value in “[-brightness, brightness]” to the brightness of image.

contrast float, optional, default=0 Add a random value in “[-contrast, contrast]” to the contrast of image.

saturation float, optional, default=0 Add a random value in “[-saturation, saturation]” to the saturation of image.

pca.noise float, optional, default=0 Add PCA based noise to the image.

random.h int, optional, default='0' Add a random value in “[-random_h, random_h]” to the H channel in HSL color space.

random.s int, optional, default='0' Add a random value in “[-random_s, random_s]” to the S channel in HSL color space.

random.l int, optional, default='0' Add a random value in “[-random_l, random_l]” to the L channel in HSL color space.

rotate int, optional, default='-1' Rotate by an angle. If set, it overwrites the “max_rotate_angle” option.

fill.value int, optional, default='255' Set the padding pixels value to “fill.value”.

data.shape Shape(tuple), required The shape of a output image.

inter.method int, optional, default='1' The interpolation method: 0-NN 1-bilinear 2-cubic 3-area 4-lanczos4 9-auto 10-rand.

pad int, optional, default='0' Change size from “[width, height]” into “[pad + width + pad, pad + height + pad]” by padding pixes

mirror boolean, optional, default=0 Whether to mirror the image or not. If true, images are flipped along the horizontal axis.

rand.mirror boolean, optional, default=0 Whether to randomly mirror images or not. If true,

\itemmean.imgstring, optional, default=" Filename of the mean image.
\itemmean.rfloat, optional, default=0 The mean value to be subtracted on the R channel
\itemmean.gfloat, optional, default=0 The mean value to be subtracted on the G channel
\itemmean.bfloat, optional, default=0 The mean value to be subtracted on the B channel
\itemmean.afloat, optional, default=0 The mean value to be subtracted on the alpha channel
\itemstd.rfloat, optional, default=1 Augmentation Param: Standard deviation on R channel.
\itemstd.gfloat, optional, default=1 Augmentation Param: Standard deviation on G channel.
\itemstd.bfloat, optional, default=1 Augmentation Param: Standard deviation on B channel.
\itemstd.afloat, optional, default=1 Augmentation Param: Standard deviation on Alpha channel.
\itemscalefloat, optional, default=1 Multiply the image with a scale value.
Iterating on image RecordIO files

Usage

mx.io.ImageRecordIter_v1(...)

Arguments

path.imglist string, optional, default="" Path to the image list (.lst) file. Generally created with tools/im2rec.py. Format (Tab separated): <index of record> <one or more labels> <relative path from root folder>.

path.imgrec string, optional, default="" Path to the image RecordIO (.rec) file or a directory path. Created with tools/im2rec.py.

path.imgidx string, optional, default="" Path to the image RecordIO index (.idx) file. Created with tools/im2rec.py.

aug.seq string, optional, default='aug_default' The augmenter names to represent sequence of augmenters to be applied, separated by comma. Additional keyword parameters will be seen by these augmenters.

label.width int, optional, default='1' The number of labels per image.

preprocess.threads int, optional, default='4' The number of threads to do preprocessing.
verbose: boolean, optional, default=1 If or not output verbose information.

num.parts: int, optional, default='1' Virtually partition the data into these many parts.

part.index: int, optional, default='0' The *i*-th virtual partition to be read.

device.id: int, optional, default='0' The device id used to create context for internal NDArr.

shuffle.chunk.size: long (non-negative), optional, default=0 The data shuffle buffer size in MB. Only valid if shuffle is true.

shuffle.chunk.seed: int, optional, default='0' The random seed for shuffling.

seed.aug: int or None, optional, default='None' Random seed for augmentations.

shuffle: boolean, optional, default=0 Whether to shuffle data randomly or not.

seed: int, optional, default='0' The random seed.

batch.size: int (non-negative), required Batch size.

round.batch: boolean, optional, default=1 Whether to use round robin to handle overflow batch or not.

prefetch.buffer: long (non-negative), optional, default=4 Maximum number of batches to prefetch.

ctx: 'cpu', 'gpu', optional, default='gpu' Context data loader optimized for.

dtype: None, 'bfloat16', 'float16', 'float32', 'float64', 'int32', 'int64', 'int8', 'uint8', optional, default='None' Output data type. "None" means no change.

resize: int, optional, default='-1' Down scale the shorter edge to a new size before applying other augmentations.

rand.crop: boolean, optional, default=0 If or not randomly crop the image.

random.resized.crop: boolean, optional, default=0 If or not perform random resized cropping on the image, as a standard preprocessing for resnet training on ImageNet data.

max.rotate.angle: int, optional, default='0' Rotate by a random degree in “[-v, v]”

max.aspect.ratio: float, optional, default=0 Change the aspect (namely width/height) to a random value. If min_aspect_ratio is None then the aspect ratio ins sampled from [1 - max_aspect_ratio, 1 + max_aspect_ratio], else it is in “[min_aspect_ratio, max_aspect_ratio]”

min.aspect.ratio: float or None, optional, default=None Change the aspect (namely width/height) to a random value in “[min_aspect_ratio, max_aspect_ratio]”

max.shear.ratio: float, optional, default=0 Apply a shear transformation (namely “(x,y)->(x+my,y)”) with “m” randomly chose from “[-max_shear_ratio, max_shear_ratio]”

max.crop.size: int, optional, default='1' Crop both width and height into a random size in “[min_crop_size, max_crop_size].” Ignored if “random_resized_crop” is True.
min.crop.size  int, optional, default=-1 Crop both width and height into a random size in "[min_crop_size, max_crop_size]." Ignored if "random_resized_crop" is True.

max.random.scale  float, optional, default=1 Resize into "[width*s, height*s]" with "s" randomly chosen from "[min_random_scale, max_random_scale]". Ignored if "random_resized_crop" is True.

min.random.scale  float, optional, default=1 Resize into "[width*s, height*s]" with "s" randomly chosen from "[min_random_scale, max_random_scale]". Ignored if "random_resized_crop" is True.

max.random.area  float, optional, default=1 Change the area (namely width * height) to a random value in "[min_random_area, max_random_area]". Ignored if "random_resized_crop" is False.

min.random.area  float, optional, default=1 Change the area (namely width * height) to a random value in "[min_random_area, max_random_area]". Ignored if "random_resized_crop" is False.

max.img.size  float, optional, default=1e+10 Set the maximal width and height after all resize and rotate argumentation are applied.

min.img.size  float, optional, default=0 Set the minimal width and height after all resize and rotate argumentation are applied.

brightness  float, optional, default=0 Add a random value in "[-brightness, brightness]" to the brightness of image.

contrast  float, optional, default=0 Add a random value in "[-contrast, contrast]" to the contrast of image.

saturation  float, optional, default=0 Add a random value in "[-saturation, saturation]" to the saturation of image.

pca.noise  float, optional, default=0 Add PCA based noise to the image.

random.h  int, optional, default=0 Add a random value in "[-random_h, random_h]" to the H channel in HSL color space.

random.s  int, optional, default=0 Add a random value in "[-random_s, random_s]" to the S channel in HSL color space.

random.l  int, optional, default=0 Add a random value in "[-random_l, random_l]" to the L channel in HSL color space.

rotate  int, optional, default=-1 Rotate by an angle. If set, it overwrites the "max_rotate_angle" option.

fill.value  int, optional, default=255 Set the padding pixels value to "fill_value".

data.shape  Shape(tuple), required The shape of a output image.

inter.method  int, optional, default=1 The interpolation method: 0-NN 1-bilinear 2-cubic 3-area 4-lanczos4 9-auto 10-rand.

pad  int, optional, default=0 Change size from "[width, height]" into "[pad + width + pad, pad + height + pad]" by padding pixes.
mirror

boolean, optional, default=0 Whether to mirror the image or not. If true, images are flipped along the horizontal axis.

rand_mirror

boolean, optional, default=0 Whether to randomly mirror images or not. If true, images are flipped along the horizontal axis.

- mean.imgstring, optional, default=“ Filename of the mean image.
- mean.rfloat, optional, default=0 The mean value to be subtracted on the R channel.
- mean.gfloat, optional, default=0 The mean value to be subtracted on the G channel.
- mean.bfloat, optional, default=0 The mean value to be subtracted on the B channel.
- mean.afloat, optional, default=0 The mean value to be subtracted on the alpha channel.

- std.rfloat, optional, default=1 Augmentation Param: Standard deviation on R channel.
- std.gfloat, optional, default=1 Augmentation Param: Standard deviation on G channel.
- std.bfloat, optional, default=1 Augmentation Param: Standard deviation on B channel.
- std.afloat, optional, default=1 Augmentation Param: Standard deviation on Alpha channel.

- scale.float, optional, default=1 Multiply the image with a scale value.

- max.random.contrastfloat, optional, default=0 Change the contrast with a value randomly chosen from “([-max_random_contrast, max_random_contrast])”

- max.random.illuminationfloat, optional, default=0 Change the illumination with a value randomly chosen from “([-max_random_illumination, max_random_illumination])”

.. note::

   “ImageRecordIter_v1” is deprecated. Use “ImageRecordIter” instead.

Read images batches from RecordIO files with a rich of data augmentation options.

One can use “tools/im2rec.py” to pack individual image files into RecordIO files.

Defined in src/io/iter_image_recordio.cc:L352

mx.io.ImageRecordUInt8Iter

Iterating on image RecordIO files

Description

.. note:: ImageRecordUInt8Iter is deprecated. Use ImageRecordIter(dtype=’uint8’) instead.
mx.io.ImageRecordUInt8Iter

Arguments

**path.imglist**
string, optional, default="" Path to the image list (.lst) file. Generally created with tools/im2rec.py. Format (Tab separated): <index of record> <one or more labels> <relative path from root folder>.

**path.imgrec**
string, optional, default="" Path to the image RecordIO (.rec) file or a directory path. Created with tools/im2rec.py.

**path.imgidx**
string, optional, default="" Path to the image RecordIO index (.idx) file. Created with tools/im2rec.py.

**aug.seq**
string, optional, default="aug_default" The augmenter names to represent sequence of augmenters to be applied, separated by comma. Additional keyword parameters will be seen by these augmenters.

**label.width**
int, optional, default='1' The number of labels per image.

**preprocess.threads**
int, optional, default='4' The number of threads to do preprocessing.

**verbose**
boolean, optional, default=1 If not output verbose information.

**num.parts**
int, optional, default='1' Virtually partition the data into these many parts.

**part.index**
int, optional, default='0' The *i*-th virtual partition to be read.

**device.id**
int, optional, default='0' The device id used to create context for internal NDArray. Setting device_id to -1 will create Context::CPU(0). Setting device_id to valid positive device id will create Context::CPUPinned(device_id). Default is 0.

**shuffle.chunk.size**
long (non-negative), optional, default=0 The data shuffle buffer size in MB. Only valid if shuffle is true.

**shuffle.chunk.seed**
int, optional, default='0' The random seed for shuffling

**seed.aug**
int or None, optional, default='None' Random seed for augmentations.

**shuffle**
boolean, optional, default=0 Whether to shuffle data randomly or not.

**seed**
int, optional, default='0' The random seed.

**batch.size**
int (non-negative), required Batch size.

**round.batch**
boolean, optional, default=1 Whether to use round robin to handle overflow batch or not.

**prefetch.buffer**
long (non-negative), optional, default=4 Maximum number of batches to prefetch.

**ctx**
'cpu', 'gpu', optional, default='gpu' Context data loader optimized for.

**dtype**
None, 'bfloat16', 'float16', 'float32', 'float64', 'int32', 'int64', 'int8', 'uint8', optional, default='None' Output data type. "None" means no change.

**resize**
int, optional, default='-1' Down scale the shorter edge to a new size before applying other augmentations.
rand.crop  boolean, optional, default=0 If or not randomly crop the image
random.resized.crop  boolean, optional, default=0 If or not perform random resized cropping on the image, as a standard preprocessing for resnet training on ImageNet data.
max.rotate.angle  int, optional, default='0' Rotate by a random degree in “[-v, v]”
max.aspect.ratio  float, optional, default=0 Change the aspect (namely width/height) to a random value. If min_aspect_ratio is None then the aspect ratio ins sampled from [1 - max_aspect_ratio, 1 + max_aspect_ratio], else it is in “[min_aspect_ratio, max_aspect_ratio]”
min.aspect.ratio  float or None, optional, default=None Change the aspect (namely width/height) to a random value in “[min_aspect_ratio, max_aspect_ratio]”
max.shear.ratio  float, optional, default=0 Apply a shear transformation (namely “(x,y)->(x+my,y)”) with “m” randomly chose from “[max_shear_ratio, max_shear_ratio]”
max.crop.size  int, optional, default=-1’ Crop both width and height into a random size in “[min_crop_size, max_crop_size].” Ignored if “random_resized_crop” is True.
min.crop.size  int, optional, default=-1’ Crop both width and height into a random size in “[min_crop_size, max_crop_size].” Ignored if “random_resized_crop” is True.
max.random.scale  float, optional, default=1 Resize into “[width*s, height*s]” with “s” randomly chosen from “[min_random_scale, max_random_scale]”. Ignored if “random_resized_crop” is True.
min.random.scale  float, optional, default=1 Resize into “[width*s, height*s]” with “s” randomly chosen from “[min_random_scale, max_random_scale]”. Ignored if “random_resized_crop” is True.
max.random.area  float, optional, default=1 Change the area (namely width * height) to a random value in “[min_random_area, max_random_area]”. Ignored if “random_resized_crop” is False.
min.random.area  float, optional, default=1 Change the area (namely width * height) to a random value in “[min_random_area, max_random_area]”. Ignored if “random_resized_crop” is False.
max.img.size  float, optional, default=1e+10 Set the maximal width and height after all resize and rotate argumentation are applied
min.img.size  float, optional, default=0 Set the minimal width and height after all resize and rotate argumentation are applied
brightness  float, optional, default=0 Add a random value in “[brightness, brightness]” to the brightness of image.
contrast  float, optional, default=0 Add a random value in “[contrast, contrast]” to the contrast of image.
saturation float, optional, default=0 Add a random value in “[-saturation, saturation]” to the saturation of image.

pca.noise float, optional, default=0 Add PCA based noise to the image.

random.h int, optional, default=’0’ Add a random value in “[-random_h, random_h]” to the H channel in HSL color space.

random.s int, optional, default=’0’ Add a random value in “[-random_s, random_s]” to the S channel in HSL color space.

random.l int, optional, default=’0’ Add a random value in “[-random_l, random_l]” to the L channel in HSL color space.

rotate int, optional, default=’-1’ Rotate by an angle. If set, it overwrites the “max_rotate_angle” option.

fill.value int, optional, default=’255’ Set the padding pixels value to “fill.value”.

data.shape Shape(tuple), required The shape of a output image.

inter.method int, optional, default=’1’ The interpolation method: 0-NN 1-bilinear 2-cubic 3-area 4-lanczos4 9-auto 10-rand.

pad int, optional, default=’0’ Change size from “[width, height]” into “[pad + width + pad, pad + height + pad]” by padding pixes

Details

This iterator is identical to “ImageRecordIter” except for using “uint8” as the data type instead of “float”.

Defined in src/io/iter_image_recordio_2.cc:L923

Value

iter The result mx.dataiter
Arguments

**path.imglist**  
string, optional, default="" Path to the image list (.lst) file. Generally created with tools/im2rec.py. Format (Tab separated): <index of record> <one or more labels> <relative path from root folder>.

**path.imgrec**  
string, optional, default="" Path to the image RecordIO (.rec) file or a directory path. Created with tools/im2rec.py.

**path.imgidx**  
string, optional, default="" Path to the image RecordIO index (.idx) file. Created with tools/im2rec.py.

**aug.seq**  
string, optional, default=’aug_default’ The augmenter names to represent sequence of augmenters to be applied, separated by comma. Additional keyword parameters will be seen by these augmenters.

**label.width**  
int, optional, default=’1’ The number of labels per image.

**preprocess.threads**  
int, optional, default=’4’ The number of threads to do preprocessing.

**verbose**  
boolean, optional, default=1 If or not output verbose information.

**num.parts**  
int, optional, default=’1’ Virtually partition the data into these many parts.

**part.index**  
int, optional, default=’0’ The *i*-th virtual partition to be read.

**device.id**  
int, optional, default=’0’ The device id used to create context for internal NDArray. Setting device_id to -1 will create Context::CPU(0). Setting device_id to valid positive device id will create Context::CPU(buffered(device_id)). Default is 0.

**shuffle.chunk.size**  
long (non-negative), optional, default=0 The data shuffle buffer size in MB. Only valid if shuffle is true.

**shuffle.chunk.seed**  
int, optional, default=’0’ The random seed for shuffling

**seed.aug**  
int or None, optional, default=’None’ Random seed for augmentations.

**shuffle**  
boolean, optional, default=0 Whether to shuffle data randomly or not.

**seed**  
int, optional, default=’0’ The random seed.

**batch.size**  
int (non-negative), required Batch size.

**round.batch**  
boolean, optional, default=1 Whether to use round robin to handle overflow batch or not.

**prefetch.buffer**  
long (non-negative), optional, default=4 Maximum number of batches to prefetch.

**ctx**  
’cpu’, ’gpu’, optional, default=’gpu’ Context data loader optimized for.

**dtype**  

**resize**  
int, optional, default=’-1’ Down scale the shorter edge to a new size before applying other augmentations.

**rand.crop**  
boolean, optional, default=0 If or not randomly crop the image

**random.resized.crop**  
boolean, optional, default=0 If or not perform random resized cropping on the image, as a standard preprocessing for resnet training on ImageNet data.
max.rotate.angle
int, optional, default=0' Rotate by a random degree in "[-v, v]"

max.aspect.ratio
float, optional, default=0 Change the aspect (namely width/height) to a random value. If min_aspect_ratio is None then the aspect ratio is sampled from [1 - max_aspect_ratio, 1 + max_aspect_ratio], else it is in "[min_aspect_ratio, max_aspect_ratio]"

min.aspect.ratio
float or None, optional, default=None Change the aspect (namely width/height) to a random value in "[min_aspect_ratio, max_aspect_ratio]"

max.shear.ratio
float, optional, default=0 Apply a shear transformation (namely "(x,y)->(x+my,y)") with “m” randomly chose from "[-max_shear_ratio, max_shear_ratio]"

max.crop.size
int, optional, default='-1' Crop both width and height into a random size in "[min_crop_size, max_crop_size]". Ignored if “random_resized_crop” is True.

min.crop.size
int, optional, default='-1' Crop both width and height into a random size in "[min_crop_size, max_crop_size]". Ignored if “random_resized_crop” is True.

max.random.scale
float, optional, default=1 Resize into “[width*s, height*s]“ with ‘s’ randomly chosen from "[min_random_scale, max_random_scale]”. Ignored if “random_resized_crop” is True.

min.random.scale
float, optional, default=1 Resize into “[width*s, height*s]“ with ‘s’ randomly chosen from "[min_random_scale, max_random_scale]”. Ignored if “random_resized_crop” is True.

max.random.area
float, optional, default=1 Change the area (namely width * height) to a random value in "[min_random_area, max_random_area]”. Ignored if “random_resized_crop” is False.

min.random.area
float, optional, default=1 Change the area (namely width * height) to a random value in "[min_random_area, max_random_area]”. Ignored if “random_resized_crop” is False.

max.img.size
float, optional, default=1e+10 Set the maximal width and height after all resize and rotate augmentation are applied

min.img.size
float, optional, default=0 Set the minimal width and height after all resize and rotate augmentation are applied

brightness
float, optional, default=0 Add a random value in “[-brightness, brightness]“ to the brightness of image.

contrast
float, optional, default=0 Add a random value in “[-contrast, contrast]“ to the contrast of image.

saturation
float, optional, default=0 Add a random value in “[-saturation, saturation]“ to the saturation of image.

pca.noise
float, optional, default=0 Add PCA based noise to the image.

random.h
int, optional, default='0' Add a random value in “[-random_h, random_h]“ to the H channel in HSL color space.

### Details

"ImageRecordUInt8Iter_v1" is deprecated. Use “ImageRecordUInt8Iter“ instead.

This iterator is identical to “ImageRecordIter“ except for using “uint8“ as the data type instead of “float“.

Defined in src/io/iter_image_recordio.cc:L377

### Value

| iter The result mx.dataiter |

---

Returns the LibSVM iterator which returns data with ‘csr’ storage type. This iterator is experimental and should be used with care.

### Description

The input data is stored in a format similar to LibSVM file format, except that the **indices are expected to be zero-based instead of one-based, and the column indices for each row are expected to be sorted in ascending order**. Details of the LibSVM format are available ‘here. <https://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/>’

### Usage

```
mx.io.LibSVMIter(...)```
Arguments

- **data.libsvm**: string, required The input zero-base indexed LibSVM data file or a directory path.
- **data.shape**: Shape(tuple), required The shape of one example.
- **label.libsvm**: string, optional, default='NULL' The input LibSVM label file or a directory path. If NULL, all labels will be read from “data.libsvm”.
- **label.shape**: Shape(tuple), optional, default=[1] The shape of one label.
- **num.parts**: int, optional, default='1' partition the data into multiple parts
- **part.index**: int, optional, default='0' the index of the part will read
- **batch.size**: int (non-negative), required Batch size.
- **round.batch**: boolean, optional, default=1 Whether to use round robin to handle overflow batch or not.
- **prefetch.buffer**: long (non-negative), optional, default=4 Maximum number of batches to prefetch.
- **ctx**: 'cpu', 'gpu', optional, default='gpu' Context data loader optimized for.
- **dtype**: None, 'bfloat16', 'float16', 'float32', 'float64', 'int32', 'int64', 'int8', 'uint8', optional, default='None' Output data type. “None” means no change.

Details

The ‘data_shape’ parameter is used to set the shape of each line of the data. The dimension of both ‘data_shape’ and ‘label_shape’ are expected to be 1.

The ‘data_libsvm’ parameter is used to set the path input LibSVM file. When it is set to a directory, all the files in the directory will be read.

When ‘label_libsvm’ is set to “NULL”, both data and label are read from the file specified by ‘data_libsvm’. In this case, the data is stored in 'csr' storage type, while the label is a 1D dense array.

The ‘LibSVMIter’ only support ‘round_batch’ parameter set to “True”. Therefore, if ‘batch_size’ is 3 and there are 4 total rows in libsvm file, 2 more examples are consumed at the first round.

When ‘num_parts’ and ‘part_index’ are provided, the data is split into ‘num_parts’ partitions, and the iterator only reads the ‘part_index’-th partition. However, the partitions are not guaranteed to be even.

‘reset()’ is expected to be called only after a complete pass of data.

Example:

```python
# Contents of libsvm file “data.t”.  1.0 0:0.5 2:1.2 -2.0 -3.0 0:0.6 1:2.4 2:1.2 4:1.2
# Creates a ‘LibSVMIter’ with ‘batch_size’=3. »> data_iter = mx.io.LibSVMIter(data_libsvm = 'data.t', data_shape = (3,), batch_size = 3) # The data of the first batch is stored in csr storage type »> batch = data_iter.next() »> csr = batch.data[0] <CSRNDArray 3x3 @cpu(0)> »> csr.asnumpy() [ [ 0.5 0. 1.2 ] [ 0. 0. 0. ] [ 0.6 2.4 1.2]] # The label of first batch »> label = batch.label[0] »> label [ 1. -2. -3.]

»> second_batch = data_iter.next() # The data of the second batch »> second_batch.data[0].asnumpy() [ [ 0. 0. -1.2 ] [ 0.5 0. 1.2 ] [ 0. 0. 0. ]] # The label of the second batch »> second_batch.label[0].asnumpy() [ 4. 1. -2.]
```
mx.io.NISTIter

Iterating on the MNIST dataset.

One can download the dataset from http://yann.lecun.com/exdb/mnist/

Arguments

<table>

</table>
mx.lr_scheduler.FactorScheduler

Learning rate scheduler. Reduction based on a factor value.

Usage

```python
mx.lr_scheduler.FactorScheduler(
    step,
    factor_val,
    stop_factor_lr = 1e-08,
    verbose = TRUE
)
```
mx.lr_scheduler.MultiFactorScheduler

Arguments

- **step** (integer) Schedule learning rate after n updates
- **factor** (double) The factor for reducing the learning rate

Value

scheduler function

__Description__

Multifactor learning rate scheduler. Reduction based on a factor value at different steps.

__Usage__

```python
mx.lr_scheduler.MultiFactorScheduler(
    step,
    factor_val,
    stop_factor_lr = 1e-08,
    verbose = TRUE
)
```

Arguments

- **step** (array of integer) Schedule learning rate after n updates
- **factor** (double) The factor for reducing the learning rate

Value

scheduler function
mx.metric.accuracy  
**Accuracy metric for classification**

**Description**

Accuracy metric for classification

**Usage**

```python
mx.metric.accuracy
```

**Format**

An object of class `mx.metric` of length 3.

mx.metric.custom  
**Helper function to create a customized metric**

**Description**

Helper function to create a customized metric

**Usage**

```python
mx.metric.custom(name, feval)
```

mx.metric.logistic_acc  
**Accuracy metric for logistic regression**

**Description**

Accuracy metric for logistic regression

**Usage**

```python
mx.metric.logistic_acc
```

**Format**

An object of class `mx.metric` of length 3.
**mx.metric.logloss**

LogLoss metric for logistic regression

---

**mx.metric.mae**

MAE (Mean Absolute Error) metric for regression

---

**mx.metric.mse**

MSE (Mean Squared Error) metric for regression
mx.metric.Perplexity  Perplexity metric for language model

Description
Perplexity metric for language model

Usage
mx.metric.Perplexity

Format
An object of class mx.metric of length 3.

mx.metric.rmse  RMSE (Root Mean Squared Error) metric for regression

Description
RMSE (Root Mean Squared Error) metric for regression

Usage
mx.metric.rmse

Format
An object of class mx.metric of length 3.

mx.metric.rmsle  RMSLE (Root Mean Squared Logarithmic Error) metric for regression

Description
RMSLE (Root Mean Squared Logarithmic Error) metric for regression

Usage
mx.metric.rmsle

Format
An object of class mx.metric of length 3.
mx.metric.top_k_accuracy

*Top-k accuracy metric for classification*

**Description**

Top-k accuracy metric for classification

**Usage**

```r
mx.metric.top_k_accuracy
```

**Format**

An object of class `mx.metric` of length 3.

---

mx.mlp

*Convenience interface for multiple layer perceptron*

**Description**

Convenience interface for multiple layer perceptron

**Usage**

```r
mx.mlp(
  data,
  label,
  hidden_node = 1,
  out_node,
  dropout = NULL,
  activation = "tanh",
  out_activation = "softmax",
  ctx = mx.ctx.default(),
  ...
)
```

**Arguments**

- `data` the input matrix. Only mx.io.DataIter and R array/matrix types supported.
- `label` the training label. Only R array type supported.
- `hidden_node` a vector containing number of hidden nodes on each hidden layer as well as the output layer.
- `out_node` the number of nodes on the output layer.
dropout a number in \([0,1)\) containing the dropout ratio from the last hidden layer to the output layer.

activation either a single string or a vector containing the names of the activation functions.

out_activation a single string containing the name of the output activation function.

ctx whether train on cpu (default) or gpu.

... other parameters passing to \texttt{mx.model.FeedForward.create/}

eval.metric the evaluation metric/

Examples

```r
require(mlbench)
data(Sonar, package="mlbench")
Sonar[,61] = as.numeric(Sonar[,61])-1
train.ind = c(1:50, 100:150)
train.x = data.matrix(Sonar[train.ind, 1:60])
train.y = Sonar[train.ind, 61]
test.x = data.matrix(Sonar[-train.ind, 1:60])
test.y = Sonar[-train.ind, 61]
model = mx.mlp(train.x, train.y, hidden_node = 10, out_node = 2, out_activation = "softmax",
learning.rate = 0.1)
preds = predict(model, test.x)
```

mx.model.buckets \hspace{1cm} \textit{Train RNN with bucket support}

Description

Train RNN with bucket support

Usage

```r
mx.model.buckets(
  symbol,
  train.data,
  eval.data = NULL,
  metric = NULL,
  arg.params = NULL,
  aux.params = NULL,
  fixed.params = NULL,
  num.round = 1,
  begin.round = 1,
  initializer = mx.init.uniform(0.01),
  optimizer = "sgd",
  ctx = NULL,
  batch.end.callback = NULL,
)```
Create a MXNet Feedforward neural net model with the specified training.

Arguments

symbol
Symbol or list of Symbols representing the model

train.data
Training data created by mx.io.bucket.iter

eval.data
Evaluation data created by mx.io.bucket.iter

num.round
int, number of epoch

verbose

Description

Create a MXNet Feedforward neural net model with the specified training.

Usage

mx.model.FeedForward.create(
    symbol,
    train.data,
    y = NULL,
    ctx = NULL,
    begin.round = 1,
    num.round = 10,
    optimizer = "sgd",
    initializer = mx.init.uniform(0.01),
    eval.data = NULL,
    eval.metric = NULL,
    epoch.end.callback = NULL,
    batch.end.callback = NULL,
    array.batch.size = 128,
    array.layout = "auto",
    kvstore = "local",
    verbose = TRUE,
    arg.params = NULL,
    aux.params = NULL,
    input.names = NULL,
    output.names = NULL,
)
mx.model.FeedForward.create

fixed.param = NULL,
allow.extra.params = FALSE,
metric_cpu = TRUE,

Arguments

symbol  The symbolic configuration of the neural network.
x  mx.io.DataIter or R array/matrix The training data.
y  R array, optional label of the data This is only used when X is R array.
ctx  mx.context or list of mx.context, optional The devices used to perform training.
begin.round  integer (default=1) The initial iteration over the training data to train the model.
um.round  integer (default=10) The number of iterations over training data to train the model.
optimizer  string, default="sgd" The optimization method.
initializer,  initializer object. default=mx.init.uniform(0.01) The initialization scheme for
eval.data  mx.io.DataIter or list(data=R.array, label=R.array), optional The validation set
used for validation evaluation during the progress
eval.metric  function, optional The evaluation function on the results.
epoch.end.callback  function, optional The callback when iteration ends.
batch.end.callback  function, optional The callback when one mini-batch iteration ends.
array.batch.size  integer (default=128) The batch size used for R array training.
array.layout  can be "auto", "colmajor", "rowmajor", (default=auto) The layout of array. "row-
  major" is only supported for two dimensional array. For matrix, "rowmajor"
  means dim(X) = c(nexample, nfeatures), "colmajor" means dim(X) = c(nfeatures,
  nexample) "auto" will auto detect the layout by match the feature size, and will
  report error when X is a square matrix to ask user to explicitly specify layout.
kvstore  string (default="local") The parameter synchronization scheme in multiple de-
  vices.
verbose  logical (default=TRUE) Specifies whether to print information on the iterations
during training.
arg.params  list, optional Model parameter, list of name to NDArray of net’s weights.
aux.params  list, optional Model parameter, list of name to NDArray of net’s auxiliary states.
input.names  optional The names of the input symbols.
output.names  optional The names of the output symbols.
fixed.param  The parameters to be fixed during training. For these parameters, not gradients
  will be calculated and thus no space will be allocated for the gradient.
allow.extra.params  Whether allow extra parameters that are not needed by symbol. If this is TRUE,
  no error will be thrown when arg.params or aux.params contain extra param-
  eters that is not needed by the executor.
mx.model.init.params

Value
model A trained mxnet model.

mx.model.init.params Parameter initialization

Description
Parameter initialization

Usage
mx.model.init.params(symbol, input.shape, output.shape, initializer, ctx)

Arguments
symbol The symbolic configuration of the neural network.
input.shape The shape of the input for the neural network.
output.shape The shape of the output for the neural network. It can be NULL.
initializer, initializer object. The initialization scheme for parameters.
ctx mx.context. The devices used to perform initialization.

mx.model.load Load model checkpoint from file.

Description
Load model checkpoint from file.

Usage
mx.model.load(prefix, iteration)

Arguments
prefix string prefix of the model name
iteration integer Iteration number of model we would like to load.
mx.model.save  

Save model checkpoint into file.

Description
Save model checkpoint into file.

Usage
mx.model.save(model, prefix, iteration)

Arguments
model  The feedforward model to be saved.
prefix  string prefix of the model name
iteration  integer Iteration number of model we would like to load.

mx.nd.abs  

Returns element-wise absolute value of the input.

Description
Example::

Arguments
data  NDArray-or-Symbol The input array.

Details
abs([-2, 0, 3]) = [2, 0, 3]
The storage type of “abs“ output depends upon the input storage type:
- abs(default) = default - abs(row_sparse) = row_sparse - abs(csr) = csr
Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L720

Value
out The result mx.ndarray
**mx.nd.Activation**

Applies an activation function element-wise to the input.

**Description**

The following activation functions are supported:

**Arguments**

- **data**: NDArray-or-Symbol The input array.
- **act.type**: 'relu', 'sigmoid', 'softrelu', 'softsign', 'tanh', required Activation function to be applied.

**Details**

- 'relu': Rectified Linear Unit, \( y = \max(x, 0) \)
- 'sigmoid': \( y = \frac{1}{1 + \exp(-x)} \)
- 'tanh': Hyperbolic tangent, \( y = \frac{\exp(x) - \exp(-x)}{\exp(x) + \exp(-x)} \)
- 'softrelu': Soft ReLU, \( y = \log(1 + \exp(x)) \)
- 'softsign': \( y = \frac{x}{1 + |x|} \)

Defined in src/operator/nn/activation.cc:L165

**Value**

- **out**: The result mx.ndarray

---

**mx.nd.adam.update**

Update function for Adam optimizer. Adam is seen as a generalization of AdaGrad.

**Description**

Adam update consists of the following steps, where \( g \) represents gradient and \( m, v \) are 1st and 2nd order moment estimates (mean and variance).

**Arguments**

- **weight**: NDArray-or-Symbol Weight
- **grad**: NDArray-or-Symbol Gradient
- **mean**: NDArray-or-Symbol Moving mean
- **var**: NDArray-or-Symbol Moving variance
- **lr**: float, required Learning rate
- **beta1**: float, optional, default=0.899999976 The decay rate for the 1st moment estimates.
beta2 float, optional, default=0.999000013 The decay rate for the 2nd moment estimates.

epsilon float, optional, default=9.99999994e-09 A small constant for numerical stability.

wd float, optional, default=0 Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.

rescale.grad float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.

clip.gradient float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient] If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).

lazy.update boolean, optional, default=1 If true, lazy updates are applied if gradient’s stype is row_sparse and all of w, m and v have the same stype.

Details
.. math::
\begin{align*}
g_t &= \nabla J(W_{t-1}) \\
m_t &= \beta_1 m_{t-1} + (1 - \beta_1) g_t \\
v_t &= \beta_2 v_{t-1} + (1 - \beta_2) g_t^2 \\
W_t &= W_{t-1} - \alpha \frac{m_t}{\sqrt{v_t} + \epsilon}
\end{align*}

It updates the weights using::

.. math::
m = \beta_1 m + (1 - \beta_1) \cdot \text{grad} \\
v = \beta_2 v + (1 - \beta_2) \cdot (\text{grad}^2) \\
w += - \text{learning_rate} \cdot \frac{m}{\sqrt{v} + \epsilon}

However, if grad’s storage type is “row_sparse”, “lazy_update” is True and the storage type of weight is the same as those of m and v, only the row slices whose indices appear in grad.indices are updated (for w, m and v):

for row in grad.indices:
    m[row] = \beta_1 \cdot m[row] + (1 - \beta_1) \cdot \text{grad}[row] \\
v[row] = \beta_2 \cdot v[row] + (1 - \beta_2) \cdot (\text{grad}[row]^2) \\
w[row] += - \text{learning_rate} \cdot \frac{m[row]}{\sqrt{v[row]} + \epsilon}

Defined in src/operator/optimizer_op.cc:L688

Value
out The result mx.ndarray

mx.nd.add.n
Adds all input arguments element-wise.

Description
.. math::
\text{add}_n(a_1, a_2, ..., a_n) = a_1 + a_2 + ... + a_n

Arguments
args NDArray-or-Symbol[] Positional input arguments
mx.nd.all.finite

**Details**

“add_n” is potentially more efficient than calling “add” by ‘n’ times.

The storage type of “add_n” output depends on storage types of inputs

- add_n(row_sparse, row_sparse, ..) = row_sparse
- add_n(default, csr, default) = default
- add_n(any input combinations longer than 4 (>4) with at least one default type) = default
- otherwise, “add_n” falls all inputs back to default storage and generates default storage

Defined in src/operator/tensor/elemwise_sum.cc:L156

**Value**

out The result mx.nd.array

---

mx.nd.all.finite **Check if all the float numbers in the array are finite (used for AMP)**

**Description**

Defined in src/operator/contrib/all_finite.cc:L101

**Arguments**

- **data** NDArray Array
- **init.output** boolean, optional, default=1 Initialize output to 1.

**Value**

out The result mx.nd.array

---

mx.nd.amp.cast **Cast function between low precision float/FP32 used by AMP.**

**Description**

It casts only between low precision float/FP32 and does not do anything for other types.

**Arguments**

- **data** NDArray-or-Symbol The input.
- **dtype** 'bfloat16', 'float16', 'float32', 'float64', 'int32', 'int64', 'int8', 'uint8', required Output data type.

**Details**

Defined in src/operator/tensor/amp_cast.cc:L121
mx.nd.arccos

Description

Returns element-wise inverse cosine of the input array.

Arguments

data (NDArray-or-Symbol) - The input array.

Details

.. math:: \text{arccos}([-1, -\sqrt{2}/2, 0, \sqrt{2}/2, 1]) = [\pi, 3\pi/4, \pi/2, \pi/4, 0]

The storage type of “arccos” output is always dense

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L233

Value

out (The result mx.ndarray) -

mx.nd.amp.multicast

Cast function used by AMP, that casts its inputs to the common widest type.

Description

It casts only between low precision float/FP32 and does not do anything for other types.

Arguments

data (NDArray-or-Symbol) - Weights
num.outputs (int, required) - Number of input/output pairs to be casted to the widest type.
cast.narrow (boolean, optional, default=0) - Whether to cast to the narrowest type

Details

Defined in src/operator/tensor/amp_cast.cc:L165

Value

out (The result mx.ndarray) -
mx.nd.arccosh

Returns the element-wise inverse hyperbolic cosine of the input array, computed element-wise.

Description
The storage type of “arccosh” output is always dense

Arguments
- data: NDArray-or-Symbol The input array.

Details
Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L535

Value
out The result mx.nd.array

mx.nd.arcsin

Returns element-wise inverse sine of the input array.

Description
The input should be in the range ‘[-1, 1]’. The output is in the closed interval of \([-\pi/2, \pi/2]\).

Arguments
- data: NDArray-or-Symbol The input array.

Details
.. math:: \text{arcsin}([-1, -.707, 0, .707, 1]) = [-\pi/2, -\pi/4, 0, \pi/4, \pi/2]

The storage type of “arcsin” output depends upon the input storage type:
- arcsin(default) = default - arcsin(row_sparse) = row_sparse - arcsin(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L187

Value
out The result mx.nd.array
mx.nd.arcsinh  

Returns the element-wise inverse hyperbolic sine of the input array, computed element-wise.

Description

The storage type of “arcsinh” output depends upon the input storage type:

Arguments

data  NDArray-or-Symbol The input array.

Details

- arcsinh(default) = default - arcsinh(row_sparse) = row_sparse - arcsinh(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L494

Value

out The result mx.ndarray

mx.nd.arctan  

Returns element-wise inverse tangent of the input array.

Description

The output is in the closed interval :math:`[-\pi/2, \pi/2]`

Arguments

data  NDArray-or-Symbol The input array.

Details

.. math:: \arctan([-1, 0, 1]) = [-\pi/4, 0, \pi/4]

The storage type of “arctan” output depends upon the input storage type:

- arctan(default) = default - arctan(row_sparse) = row_sparse - arctan(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L282

Value

out The result mx.ndarray
mx.nd.arctanh

Returns the element-wise inverse hyperbolic tangent of the input array, computed element-wise.

Description

The storage type of “arctanh” output depends upon the input storage type:

Arguments

data NDArray-or-Symbol The input array.

Details

- arctanh(default) = default - arctanh(row_sparse) = row_sparse - arctanh(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L579

Value

out The result mx.ndarray

mx.nd.argmax

Returns indices of the maximum values along an axis.

Description

In the case of multiple occurrences of maximum values, the indices corresponding to the first occurrence are returned.

Arguments

data NDArray-or-Symbol The input
axis int or None, optional, default=’None’ The axis along which to perform the reduction. Negative values means indexing from right to left. “Requires axis to be set as int, because global reduction is not supported yet.“
keepdims boolean, optional, default=0 If this is set to ‘True’, the reduced axis is left in the result as dimension with size one.
**mx.nd.argmax.channel**

**Details**

Examples:

```
x = [[[  0.,  1.,  2.], [  3.,  4.,  5.]]

// argmax along axis 0
argmax(x, axis=0) = [[  1.,  1.,  1.]]

// argmax along axis 1
argmax(x, axis=1) = [[  2.], [  2.]]

// argmax along axis 1 keeping same dims as an input array
argmax(x, axis=1, keepdims=True) = [[[  2.], [  2.]]]
```

Defined in `src/operator/tensor/broadcast_reduce_op_index.cc:L52`

**Value**

```
out The result mx.ndarray
```

**mx.nd.argmax.channel**  
*Returns argmax indices of each channel from the input array.*

**Description**

The result will be an NDArray of shape (num_channel,).

**Arguments**

- **data**  
  NDArray-or-Symbol  
  The input array

**Details**

In case of multiple occurrences of the maximum values, the indices corresponding to the first occurrence are returned.

Examples:

```
x = [[[  0.,  1.,  2.], [  3.,  4.,  5.]]
argmax_channel(x) = [[  2.], [  2.]]
```

Defined in `src/operator/tensor/broadcast_reduce_op_index.cc:L97`

**Value**

```
out The result mx.ndarray
```

\section*{mx.nd.argmin}

\textit{Returns indices of the minimum values along an axis.}

\subsection*{Description}

In the case of multiple occurrences of minimum values, the indices corresponding to the first occurrence are returned.

\subsection*{Arguments}

\begin{itemize}
  \item \textbf{data} : NDArray-or-Symbol The input
  \item \textbf{axis} : int or None, optional, default='None' The axis along which to perform the reduction. Negative values means indexing from right to left. “Requires axis to be set as int, because global reduction is not supported yet.”
  \item \textbf{keepdims} : boolean, optional, default=0 If this is set to ‘True’, the reduced axis is left in the result as dimension with size one.
\end{itemize}

\subsection*{Details}

Examples:

\begin{verbatim}
x = [[ 0., 1., 2.], [ 3., 4., 5.]]
// argmin along axis 0 argmin(x, axis=0) = [ 0., 0., 0.]
// argmin along axis 1 argmin(x, axis=1) = [ 0., 0.]
// argmin along axis 1 keeping same dims as an input array argmin(x, axis=1, keepdims=True) = [[ 0.], [ 0.]]
\end{verbatim}

Defined in src/operator/tensor/broadcast_reduce_op_index.cc:L77

\subsection*{Value}

\begin{itemize}
  \item \textbf{out} : The result mx.ndarray
\end{itemize}

\section*{mx.nd.argsort}

\textit{Returns the indices that would sort an input array along the given axis.}

\subsection*{Description}

This function performs sorting along the given axis and returns an array of indices having same shape as an input array that index data in sorted order.
Arguments

data NDArray-or-Symbol The input array
axis int or None, optional, default=-1 Axis along which to sort the input tensor. If not given, the flattened array is used. Default is -1.
is.ascend boolean, optional, default=1 Whether to sort in ascending or descending order.
dtype 'float16', 'float32', 'float64', 'int32', 'int64', 'uint8',optional, default='float32' DType of the output indices. It is only valid when ret_typ is "indices" or "both". An error will be raised if the selected data type cannot precisely represent the indices.

Details

Examples::
x = [[ 0.3, 0.2, 0.4], [ 0.1, 0.3, 0.2]]
// sort along axis -1 argsort(x) = [[ 1., 0., 2.], [ 0., 2., 1.]]
// sort along axis 0 argsort(x, axis=0) = [[ 1., 0., 1.0], [ 0., 1., 0.]]
// flatten and then sort argsort(x, axis=None) = [ 3., 1., 5., 0., 4., 2.]
Defined in src/operator/tensor/ordering_op.cc:L185

Value

out The result mx.ndarray

mx.nd.array Create a new mx.ndarray that copies the content from src on ctx.

Description

Create a new mx.ndarray that copies the content from src on ctx.

Usage

mx.nd.array(src.array, ctx = NULL)

Arguments

src.array Source array data of class array, vector or matrix.
ctx optional The context device of the array. mx.ctx.default() will be used in default.

Value

An mx.ndarray
An Rcpp_MXNDArray object
Examples

```python
mat = mx.nd.array(x)
mat = 1 - mat + (2 * mat)/(mat + 0.5)
as.array(mat)
```

mx.nd.batch.dot

Batchwise dot product.

Description

“batch_dot” is used to compute dot product of “x” and “y” when “x” and “y” are data in batch, namely N-D (N >= 3) arrays in shape of ‘(B0, ..., B_i, :, :)'.

Arguments

- **lhs**: NDArray-or-Symbol The first input
- **rhs**: NDArray-or-Symbol The second input
- **transpose.a**: boolean, optional, default=0 If true then transpose the first input before dot.
- **transpose.b**: boolean, optional, default=0 If true then transpose the second input before dot.
- **forward.stype**: None, 'csr', 'default', 'row_sparse', optional, default='None' The desired storage type of the forward output given by user, if the combination of input storage types and this hint does not match any implemented ones, the dot operator will perform fallback operation and still produce an output of the desired storage type.

Details

For example, given “x” with shape ‘(B_0, ..., B_i, N, M)’ and “y” with shape ‘(B_0, ..., B_i, M, K)’, the result array will have shape ‘(B_0, ..., B_i, N, K)’, which is computed by:

```
batch_dot(x,y)[b_0, ..., b_i, :, :] = dot(x[b_0, ..., b_i, :, :], y[b_0, ..., b_i, :, :])
```

Defined in src/operator/tensor/dot.cc:L127

Value

- **out**: The result mx.ndarray
mx.nd.BatchNorm

Batch normalization.

Description

Normalizes a data batch by mean and variance, and applies a scale "gamma" as well as offset "beta".

Arguments

data NDArray-or-Symbol Input data to batch normalization

gamma NDArray-or-Symbol gamma array

beta NDArray-or-Symbol beta array

moving.mean NDArray-or-Symbol running mean of input

moving.var NDArray-or-Symbol running variance of input

eps double, optional, default=0.0010000000474974513 Epsilon to prevent div 0. Must be no less than CUDNN_BN_MIN_EPSILON defined in cudnn.h when using cudnn (usually 1e-5)

mx.nd.batch.take Takes elements from a data batch.

Description

.. note:: 'batch_take' is deprecated. Use 'pick' instead.

Arguments

a NDArray-or-Symbol The input array

indices NDArray-or-Symbol The index array

Details

Given an input array of shape "(d0, d1)" and indices of shape "(i0,)", the result will be an output array of shape "(i0,)" with:

output[i] = input[i, indices[i]]

Examples::

x = [[ 1., 2.], [ 3., 4.], [ 5., 6.]]
// takes elements with specified indices batch_take(x, [0,1,0]) = [ 1. 4. 5.]

Defined in src/operator/tensor/indexing_op.cc:L836

Value

out The result mx.nd.array
**mx.nd.BatchNorm**

- **momentum**: float, optional, default=0.899999976 Momentum for moving average
- **fix.gamma**: boolean, optional, default=1 Fix gamma while training
- **use.global.stats**: boolean, optional, default=0 Whether use global moving statistics instead of local batch-norm. This will force change batch-norm into a scale shift operator.
- **output.mean.var**: boolean, optional, default=0 Output the mean and inverse std
- **axis**: int, optional, default=’1’ Specify which shape axis the channel is specified
- **cudnn.off**: boolean, optional, default=0 Do not select CUDNN operator, if available
- **min.calib.range**: float or None, optional, default=None The minimum scalar value in the form of float32 obtained through calibration. If present, it will be used to by quantized batch norm op to calculate primitive scale. Note: this calib_range is to calib bn output.
- **max.calib.range**: float or None, optional, default=None The maximum scalar value in the form of float32 obtained through calibration. If present, it will be used to by quantized batch norm op to calculate primitive scale. Note: this calib_range is to calib bn output.

**Details**

Assume the input has more than one dimension and we normalize along axis 1. We first compute the mean and variance along this axis:

```
.. math::
data\_mean[i] = mean(data[:,i,:,...]) \ data\_var[i] = var(data[:,i,:,...])
```

Then compute the normalized output, which has the same shape as input, as following:

```
.. math::
out[:,i,:,...] = \frac{data[:,i,:,...]}{\sqrt{data\_var[i]}+\epsilon} * gamma[i] + beta[i]
```

Both *mean* and *var* returns a scalar by treating the input as a vector.

Assume the input has size *k* on axis 1, then both “gamma” and “beta” have shape *(k,)*. If “output_mean_var” is set to be true, then outputs both “data_mean” and the inverse of “data_var”, which are needed for the backward pass. Note that gradient of these two outputs are blocked.

Besides the inputs and the outputs, this operator accepts two auxiliary states, “moving_mean” and “moving_var”, which are *k*-length vectors. They are global statistics for the whole dataset, which are updated by:

```
moving_mean = moving_mean * momentum + data\_mean * (1 - momentum)
moving_var = moving_var * momentum + data\_var * (1 - momentum)
```

If “use_global_stats” is set to be true, then “moving_mean” and “moving_var” are used instead of “data_mean” and “data_var” to compute the output. It is often used during inference.

The parameter “axis” specifies which axis of the input shape denotes the 'channel' (separately normalized groups). The default is 1. Specifying -1 sets the channel axis to be the last item in the input shape.
Both “gamma” and “beta” are learnable parameters. But if “fix.gamma” is true, then set “gamma” to 1 and its gradient to 0.

.. Note:: When “fix.gamma“ is set to True, no sparse support is provided. If “fix.gamma is“ set to False, the sparse tensors will fallback.

Defined in src/operator/nn/batch_norm.cc:L607

Value

out The result mx.ndarray

mx.nd.BatchNorm.v1  Batch normalization.

Description

This operator is DEPRECATED. Perform BatchNorm on the input.

Arguments

data  NDArray-or-Symbol Input data to batch normalization

gamma NDArray-or-Symbol gamma array

beta  NDArray-or-Symbol beta array

eps  float, optional, default=0.00100000005 Epsilon to prevent div 0

momentum float, optional, default=0.899999976 Momentum for moving average

fix.gamma boolean, optional, default=1 Fix gamma while training

use.global.stats boolean, optional, default=0 Whether use global moving statistics instead of local batch-norm. This will force change batch-norm into a scale shift operator.

output.mean.var boolean, optional, default=0 Output All,normal mean and var

Details

Normalizes a data batch by mean and variance, and applies a scale “gamma” as well as offset “beta“. Assume the input has more than one dimension and we normalize along axis 1. We first compute the mean and variance along this axis:

.. math::

\text{data\\_mean[i]} = \text{mean(data[:,i,:,:,...])} \\
\text{data\\_var[i]} = \text{var(data[:,i,:,:,...])}

Then compute the normalized output, which has the same shape as input, as following:

.. math::

\text{out[:,i,:,:,...]} = \frac{\text{data[:,i,:,:,...]} - \text{data\\_mean[i]}\sqrt{\text{data\\_var[i]} + \text{epsilon}} * \text{gamma[i]} + \text{beta[i]}}

Both *mean* and *var* returns a scalar by treating the input as a vector.
Assume the input has size \(k\) on axis 1, then both “gamma” and “beta” have shape \((k,)\). If “output_mean_var” is set to be true, then outputs both “data_mean” and “data_var” as well, which are needed for the backward pass.

Besides the inputs and the outputs, this operator accepts two auxiliary states, “moving_mean” and “moving_var”, which are \(k\)-length vectors. They are global statistics for the whole dataset, which are updated by:

\[
\text{moving_mean} = \text{moving_mean} \times \text{momentum} + \text{data_mean} \times (1 - \text{momentum}) \\
\text{moving_var} = \text{moving_var} \times \text{momentum} + \text{data_var} \times (1 - \text{momentum})
\]

If “use_global_stats” is set to be true, then “moving_mean” and “moving_var” are used instead of “data_mean” and “data_var” to compute the output. It is often used during inference.

Both “gamma” and “beta” are learnable parameters. But if “fix_gamma” is true, then set “gamma” to 1 and its gradient to 0.

There’s no sparse support for this operator, and it will exhibit problematic behavior if used with sparse tensors.

Defined in src/operator/batch_norm_v1.cc:L95

Value

out The result mx.ndarray

---

**mx.nd.BilinearSampler** Applies bilinear sampling to input feature map.

**Description**

Bilinear Sampling is the key of [NIPS2015] "Spatial Transformer Networks". The usage of the operator is very similar to remap function in OpenCV, except that the operator has the backward pass.

**Arguments**

- **data**
  - NDArray-or-Symbol Input data to the BilinearsamplerOp.

- **grid**
  - NDArray-or-Symbol Input grid to the BilinearsamplerOp. grid has two channels: x_src, y_src

- **cudnn_off**
  - boolean or None, optional, default= None whether to turn cudnn off

**Details**

Given \(\text{:math:`data` and :math:`grid`}\), then the output is computed by

\[
\begin{align*}
  x_{src} = & \text{grid[batch, 0, y_dst, x_dst]} \\
  y_{src} = & \text{grid[batch, 1, y_dst, x_dst]} \\
  \text{output[batch, channel, y_dst, x_dst]} = & \text{G(data[batch, channel, y_src, x_src])}
\end{align*}
\]

\(x_{dst}, y_{dst}\) enumerate all spatial locations in \(\text{output}\), and \(\text{G()}\) denotes the bilinear interpolation kernel. The out-boundary points will be padded with zeros. The shape of the output will be (data.shape[0], data.shape[1], grid.shape[2], grid.shape[3]).
The operator assumes that :math:`\text{`data'} has 'NCHW' layout and :math:`\text{`grid'} has been normalized to [-1, 1].

BilinearSampler often cooperates with GridGenerator which generates sampling grids for BilinearSampler. GridGenerator supports two kinds of transformation: “affine” and “warp”. If users want to design a CustomOp to manipulate :math:`\text{`grid'}, please firstly refer to the code of GridGenerator.

Example 1::

## Zoom out data two times
```python
data = array([[[1, 4, 3, 6], [1, 8, 8, 9], [0, 4, 1, 5], [1, 0, 1, 3]]])
affine_matrix = array([[2, 0, 0], [0, 2, 0]])
affine_matrix = reshape(affine_matrix, shape=(1, 6))
grid = GridGenerator(data=affine_matrix, transform_type='affine', target_shape=(4, 4))
out = BilinearSampler(data, grid)
out = array([[[ 0, 0, 0, 0], [ 0, 3.5, 6.5, 0], [ 0, 1.25, 2.5, 0], [ 0, 0, 0, 0]]])
```

Example 2::

## shift data horizontally by -1 pixel
```python
data = array([[[1, 4, 3, 6], [1, 8, 8, 9], [0, 4, 1, 5], [1, 0, 1, 3]]])
warp_matrix = array([[[1, 1, 1, 1], [1, 1, 1, 1], [1, 1, 1, 1], [1, 1, 1, 1]], [[0, 0, 0, 0], [0, 0, 0, 0], [0, 0, 0, 0], [0, 0, 0, 0]]])
grid = GridGenerator(data=warp_matrix, transform_type='warp')
out = BilinearSampler(data, grid)
out = array([[[ 4, 3, 6, 0], [ 8, 8, 9, 0], [ 4, 1, 5, 0], [ 0, 1, 3, 0]]])
```

Defined in src/operator/bilinear_sampler.cc:L256

Value

out The result mx.nd.array

mx.nd.BlockGrad

**Stops gradient computation.**

Description

Stops the accumulated gradient of the inputs from flowing through this operator in the backward direction. In other words, this operator prevents the contribution of its inputs to be taken into account for computing gradients.

Arguments

data NDArray-or-Symbol The input array.
mx.nd.broadcast.add

Details

Example::
v1 = [1, 2] v2 = [0, 1] a = Variable('a') b = Variable('b') b_stop_grad = stop_gradient(3 * b) loss = MakeLoss(b_stop_grad + a)
executor = loss.simple_bind(ctx=cpu(), a=(1,2), b=(1,2)) executor.forward(is_train=True, a=v1, b=v2)
executor.outputs [ 1. 5.]
executor.backward() executor.grad_arrays [ 0. 0.] [ 1. 1.]
Defined in src/operator/tensor/elemental_op_basic.cc:L325

Value
out The result mx.ndarray

mx.nd.broadcast.add  
Returns element-wise sum of the input arrays with broadcasting.

Description

‘broadcast_plus’ is an alias to the function ‘broadcast_add’.

Arguments

lhs NDArray-or-Symbol First input to the function
rhs NDArray-or-Symbol Second input to the function

Details

Example::
x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]
broadcast_add(x, y) = [[ 1., 1., 1.], [ 2., 2., 2.]]
broadcast_plus(x, y) = [[ 1., 1., 1.], [ 2., 2., 2.]]
Supported sparse operations:
broadcast_add(csr, dense(1D)) = dense broadcast_add(dense(1D), csr) = dense
Defined in src/operator/tensor/elemental_binary_broadcast_op_basic.cc:L58

Value
out The result mx.ndarray
Broadcasting is allowed on axes with size 1, such as from ‘(2,1,3,1)’ to ‘(2,8,3,9)’. Elements will be duplicated on the broadcasted axes.

Arguments

- **data**: NDArray-or-Symbol The input
- **axis**: Shape(tuple), optional, default=[] The axes to perform the broadcasting.
- **size**: Shape(tuple), optional, default=[] Target sizes of the broadcasting axes.

Details

’discard_axes’ is an alias to the function ‘broadcast_axis’.

Example:

```markdown
// given x of shape (1,2,1) x = [[1.], [2.]]
// broadcast x on axis 2 broadcast_axis(x, axis=2, size=3) = [[[1., 1., 1.], [2., 2., 2.]]] // broadcast x on axes 0 and 2 broadcast_axis(x, axis=(0,2), size=(2,3)) = [[[1., 1., 1.], [2., 2., 2.]], [[1., 1., 1.], [2., 2., 2.]]]
```

Value

- **out**: The result mx.ndarray
mx.nd.broadcast.div

Details

‘broadcast_axes’ is an alias to the function ‘broadcast_axis’.

Example::

// given x of shape (1,2,1) x = [[[ 1.], [ 2.]]]
// broadcast x on on axis 2 broadcast_axis(x, axis=2, size=3) = [[[ 1., 1., 1.], [ 2., 2., 2.]]]
// broadcast x on on axes 0 and 2 broadcast_axis(x, axis=(0,2), size=(3,3)) = [[[ 1., 1., 1.], [ 2., 2., 2.]], [[ 1., 1., 1.], [ 2., 2., 2.]]]

Defined in src/operator/tensor/broadcast_reduce_op_value.cc:L93

Value

out The result mx.ndarray

mx.nd.broadcast.div

Returns element-wise division of the input arrays with broadcasting.

Description

Example::

Arguments

lhs

NDArray-or-Symbol First input to the function

rhs

NDArray-or-Symbol Second input to the function

Details

x = [[ 6., 6., 6.], [ 6., 6., 6.]]
y = [[ 2.], [ 3.]]
broadcast_div(x, y) = [[ 3., 3., 3.], [ 2., 2., 2.]]

Supported sparse operations:
broadcast_div(csr, dense(1D)) = csr

Defined in src/operator/tensor/elemwise_binary_broadcast_op_basic.cc:L187

Value

out The result mx.ndarray
mx.nd.broadcast.equal

*Returns the result of element-wise **equal to** (==) comparison operation with broadcasting.*

**Description**

Example::

Arguments

- **lhs**: NDArray-or-Symbol First input to the function
- **rhs**: NDArray-or-Symbol Second input to the function

**Details**

\[ x = \begin{bmatrix} 1., 1., 1. \\ 1., 1., 1. \end{bmatrix} \]
\[ y = \begin{bmatrix} 0. \\ 1. \end{bmatrix} \]

\[ \text{broadcast\_equal}(x, y) = \begin{bmatrix} 0., 0., 0. \\ 1., 1., 1. \end{bmatrix} \]

Defined in src/operator/tensor/elemwise_binary_broadcast_op_logic.cc:L46

**Value**

- **out**: The result mx.ndarray

mx.nd.broadcast.greater

*Returns the result of element-wise **greater than** (> ) comparison operation with broadcasting.*

**Description**

Example::

Arguments

- **lhs**: NDArray-or-Symbol First input to the function
- **rhs**: NDArray-or-Symbol Second input to the function

**Details**

\[ x = \begin{bmatrix} 1., 1., 1. \\ 1., 1., 1. \end{bmatrix} \]
\[ y = \begin{bmatrix} 0. \\ 1. \end{bmatrix} \]

\[ \text{broadcast\_greater}(x, y) = \begin{bmatrix} 1., 1., 1. \\ 0., 0., 0. \end{bmatrix} \]

Defined in src/operator/tensor/elemwise_binary_broadcast_op_logic.cc:L82
mx.nd.broadcast.greater.equal

Returns the result of element-wise **greater than or equal to** (\(\geq\)) comparison operation with broadcasting.

Description

Example::

Arguments

lhs  
NDArray-or-Symbol First input to the function

rhs  
NDArray-or-Symbol Second input to the function

Details

\[
x = [[ 1., 1., 1.], [ 1., 1., 1.]]
\]
\[
y = [[ 0.], [ 1.]]
\]

broadcast_greater_equal(x, y) = [[ 1., 1., 1.], [ 1., 1., 1.]]

Defined in `src/operator/tensor/elemwise_binary_broadcast_op_logic.cc:L100`

mx.nd.broadcast.hypot

Returns the hypotenuse of a right angled triangle, given its "legs" with broadcasting.

Description

It is equivalent to doing :math:`\sqrt{x_1^2 + x_2^2}`.

Arguments

lhs  
NDArray-or-Symbol First input to the function

rhs  
NDArray-or-Symbol Second input to the function
mx.nd.broadcast.lesser

**Details**

Example::

\[ x = \begin{bmatrix} 3., 3., 3. \end{bmatrix} \]
\[ y = \begin{bmatrix} 4. \end{bmatrix}, \begin{bmatrix} 4. \end{bmatrix} \]
\[ \text{broadcast_hypot}(x, y) = \begin{bmatrix} 5., 5., 5. \end{bmatrix}, \begin{bmatrix} 5., 5., 5. \end{bmatrix} \]
\[ z = \begin{bmatrix} 0. \end{bmatrix}, \begin{bmatrix} 4. \end{bmatrix} \]
\[ \text{broadcast_hypot}(x, z) = \begin{bmatrix} 3., 3., 3. \end{bmatrix}, \begin{bmatrix} 5., 5., 5. \end{bmatrix} \]

Defined in src/operator/tensor/elemwise_binary_broadcast_op_extended.cc:L158

**Value**

\text{out} The result mx.ndarray

---

**mx.nd.broadcast.lesser**

*Returns the result of element-wise **lesser than** (<) comparison operation with broadcasting.*

---

**Description**

Example::

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lhs</td>
<td>NDArray-or-Symbol First input to the function</td>
</tr>
<tr>
<td>rhs</td>
<td>NDArray-or-Symbol Second input to the function</td>
</tr>
</tbody>
</table>

**Details**

\[ x = \begin{bmatrix} 1., 1., 1. \end{bmatrix}, \begin{bmatrix} 1., 1., 1. \end{bmatrix} \]
\[ y = \begin{bmatrix} 0. \end{bmatrix}, \begin{bmatrix} 1. \end{bmatrix} \]
\[ \text{broadcast_lesser}(x, y) = \begin{bmatrix} 0., 0., 0. \end{bmatrix}, \begin{bmatrix} 0., 0., 0. \end{bmatrix} \]

Defined in src/operator/tensor/elemwise_binary_broadcast_op_logic.cc:L118

**Value**

\text{out} The result mx.ndarray
mx.nd.broadcast.lesser.equal

Returns the result of element-wise "less than or equal to" (<=) comparison operation with broadcasting.

Description

Example::

Arguments

lh
NDArray-or-Symbol First input to the function
rh
NDArray-or-Symbol Second input to the function

Details

\[ x = \begin{bmatrix} 1, & 1, & 1 \end{bmatrix}, \begin{bmatrix} 1, & 1, & 1 \end{bmatrix} \]
\[ y = \begin{bmatrix} 0 \end{bmatrix}, \begin{bmatrix} 1 \end{bmatrix} \]

broadcast_lesser_equal(x, y) = \begin{bmatrix} 0, & 0, & 0 \end{bmatrix}, \begin{bmatrix} 1, & 1, & 1 \end{bmatrix} \]

Defined in src/operator/tensor/elemwise_binary_broadcast_op_logic.cc:L136

Value

out The result mx.ndarray

mx.nd.broadcast.like

Broadcasts lhs to have the same shape as rhs.

Description

Broadcasting is a mechanism that allows NDArrays to perform arithmetic operations with arrays of different shapes efficiently without creating multiple copies of arrays. Also see, 'Broadcasting <https://docs.scipy.org/doc/numpy/user/basics.broadcasting.html>' for more explanation.

Arguments

lh
NDArray-or-Symbol First input.
rh
NDArray-or-Symbol Second input.
lhs.axes
Shape or None, optional, default=None Axes to perform broadcast on in the first input array
rhs.axes
Shape or None, optional, default=None Axes to copy from the second input array
Details

Broadcasting is allowed on axes with size 1, such as from `(2,1,3,1)` to `(2,8,3,9)`. Elements will be duplicated on the broadcasted axes.

For example:

- `broadcast_like([[1,2,3]], [[5,6,7],[7,8,9]]) = [[ 1., 2., 3.], [ 1., 2., 3.]]`
- `broadcast_like([9], [1,2,3,4,5], lhs_axes=(0,), rhs_axes=(-1,)) = [9,9,9,9,9]`

Defined in src/operator/tensor/broadcast_reduce_op_value.cc:L179

Value

`out` The result mx.ndarray

```
mx.nd.broadcast.logical.and

Returns the result of element-wise **logical and** with broadcasting.
```

Description

Example::

Arguments

- **lhs**: NDArray-or-Symbol First input to the function
- **rhs**: NDArray-or-Symbol Second input to the function

Details

```python
x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]
broadcast_logical_and(x, y) = [[ 0., 0., 0.], [ 1., 1., 1.]]
```

Defined in src/operator/tensor/elemwise_binary_broadcast_op_logic.cc:L154

Value

`out` The result mx.ndarray
\textbf{mx.nd.broadcast.logical.or}  

\textit{Returns the result of element-wise **logical or** with broadcasting.}

\textbf{Description}

Example::

\textbf{Arguments}

- \texttt{lhs} \hspace{1cm} NDArray-or-Symbol First input to the function
- \texttt{rhs} \hspace{1cm} NDArray-or-Symbol Second input to the function

\textbf{Details}

\begin{align*}
x &= \begin{bmatrix} 1., & 1., & 0. \end{bmatrix}, \begin{bmatrix} 1., & 1., & 0. \end{bmatrix} \\
y &= \begin{bmatrix} 1. \end{bmatrix}, \begin{bmatrix} 0. \end{bmatrix} \\
broadcast\_logical\_or(x, y) &= \begin{bmatrix} 1., & 1., & 1. \end{bmatrix}, \begin{bmatrix} 1., & 1., & 0. \end{bmatrix} 
\end{align*}

Defined in src/operator/tensor/elemwise_binary_broadcast_op_logic.cc:L172

\textbf{Value}

- \texttt{out} \hspace{1cm} The result \texttt{mx.nd.array}

---

\textbf{mx.nd.broadcast.logical.xor}  

\textit{Returns the result of element-wise **logical xor** with broadcasting.}

\textbf{Description}

Example::

\textbf{Arguments}

- \texttt{lhs} \hspace{1cm} NDArray-or-Symbol First input to the function
- \texttt{rhs} \hspace{1cm} NDArray-or-Symbol Second input to the function

\textbf{Details}

\begin{align*}
x &= \begin{bmatrix} 1., & 1., & 0. \end{bmatrix}, \begin{bmatrix} 1., & 1., & 0. \end{bmatrix} \\
y &= \begin{bmatrix} 1. \end{bmatrix}, \begin{bmatrix} 0. \end{bmatrix} \\
broadcast\_logical\_xor(x, y) &= \begin{bmatrix} 0., & 0., & 1. \end{bmatrix}, \begin{bmatrix} 1., & 1., & 0. \end{bmatrix} 
\end{align*}

Defined in src/operator/tensor/elemwise_binary_broadcast_op_logic.cc:L190
**Value**

out The result mx.ndarray

---

**mx.nd.broadcast.maximum**

*Returns element-wise maximum of the input arrays with broadcasting.*

**Description**

This function compares two input arrays and returns a new array having the element-wise maxima.

**Arguments**

- **lhs**: NDArray-or-Symbol First input to the function
- **rhs**: NDArray-or-Symbol Second input to the function

**Details**

Example:

\[
\begin{align*}
x &= \begin{bmatrix} 1., 1., 1. \\ 1., 1., 1. \end{bmatrix} \\
y &= \begin{bmatrix} 0. \\ 1. \end{bmatrix}
\end{align*}
\]

broadcast\_maximum(x, y) = \begin{bmatrix} 1., 1., 1. \\ 1., 1., 1. \end{bmatrix}

Defined in src/operator/tensor/elemwise_binary_broadcast_op_extended.cc:L81

**Value**

out The result mx.ndarray

---

**mx.nd.broadcast.minimum**

*Returns element-wise minimum of the input arrays with broadcasting.*

**Description**

This function compares two input arrays and returns a new array having the element-wise minima.

**Arguments**

- **lhs**: NDArray-or-Symbol First input to the function
- **rhs**: NDArray-or-Symbol Second input to the function
mx.nd.broadcast.minus

Details

Example:
\[ x = \begin{bmatrix} 1., & 1., & 1. \\ 1., & 1., & 1. \end{bmatrix} \]
\[ y = \begin{bmatrix} 0. \\ 1. \end{bmatrix} \]
broadcast_maximum(x, y) = \begin{bmatrix} 0., & 0., & 0. \\ 1., & 1., & 1. \end{bmatrix}
Defined in src/operator/tensor/elemwise_binary_broadcast_op_extended.cc:L117

Value

out The result mx.ndarray

mx.nd.broadcast.minus  \( \text{Returns element-wise difference of the input arrays with broadcasting.} \)

Description

‘broadcast_minus’ is an alias to the function ‘broadcast_sub’.

Arguments

\begin{itemize}
\item \textbf{lhs} \quad \text{NDArray-or-Symbol} \quad \text{First input to the function}
\item \textbf{rhs} \quad \text{NDArray-or-Symbol} \quad \text{Second input to the function}
\end{itemize}

Details

Example:
\[ x = \begin{bmatrix} 1., & 1., & 1. \\ 1., & 1., & 1. \end{bmatrix} \]
\[ y = \begin{bmatrix} 0. \\ 1. \end{bmatrix} \]
broadcast_sub(x, y) = \begin{bmatrix} 1., & 1., & 1. \\ 0., & 0., & 0. \end{bmatrix}
broadcast_minus(x, y) = \begin{bmatrix} 1., & 1., & 1. \\ 0., & 0., & 0. \end{bmatrix}
Supported sparse operations:
broadcast_sub/minus(csr, dense(1D)) = dense broadcast_sub/minus(dense(1D), csr) = dense
Defined in src/operator/tensor/elemwise_binary_broadcast_op_basic.cc:L106

Value

out The result mx.ndarray
**Description**

Example:

**Arguments**

- **lhs**: NDArray-or-Symbol First input to the function
- **rhs**: NDArray-or-Symbol Second input to the function

**Details**

\[ x = \begin{bmatrix} 8., 8., 8. \\ 8., 8., 8. \end{bmatrix} \]
\[ y = \begin{bmatrix} 2. \\ 3. \end{bmatrix} \]

\[ \text{broadcast\_mod}(x, y) = \begin{bmatrix} 0., 0., 0. \\ 2., 2., 2. \end{bmatrix} \]

Defined in src/operator/tensor/elemwise_binary_broadcast_op_basic.cc:L222

**Value**

out The result mx.ndarray

**Description**

Example:

**Arguments**

- **lhs**: NDArray-or-Symbol First input to the function
- **rhs**: NDArray-or-Symbol Second input to the function

**Details**

\[ x = \begin{bmatrix} 1., 1., 1. \\ 1., 1., 1. \end{bmatrix} \]
\[ y = \begin{bmatrix} 0. \\ 1. \end{bmatrix} \]

\[ \text{broadcast\_mul}(x, y) = \begin{bmatrix} 0., 0., 0. \\ 1., 1., 1. \end{bmatrix} \]

Supported sparse operations:

\[ \text{broadcast\_mul}(\text{csr}, \text{dense}(1D)) = \text{csr} \]

Defined in src/operator/tensor/elemwise_binary_broadcast_op_basic.cc:L146
**mx.nd.broadcast.not.equal**

*Returns the result of element-wise **not equal to** (!=) comparison operation with broadcasting.*

**Description**

Example::

**Arguments**

<table>
<thead>
<tr>

mx.nd.broadcast.power

Details

Example::

x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]

broadcast_add(x, y) = [[ 1., 1., 1.], [ 2., 2., 2.]]
broadcast_plus(x, y) = [[ 1., 1., 1.], [ 2., 2., 2.]]

Supported sparse operations:
broadcast_add(csr, dense(1D)) = dense broadcast_add(dense(1D), csr) = dense

Defined in src/operator/tensor/elemwise_binary_broadcast_op_basic.cc:L58

Value

out The result mx.ndarray

mx.nd.broadcast.power  Returns result of first array elements raised to powers from second array, element-wise with broadcasting.

Description

Example::

Arguments

lhs NDArray-or-Symbol First input to the function
rhs NDArray-or-Symbol Second input to the function

Details

x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]

broadcast_power(x, y) = [[ 2., 2., 2.], [ 4., 4., 4.]]

Defined in src/operator/tensor/elemwise_binary_broadcast_op_extended.cc:L45

Value

out The result mx.ndarray
**mx.nd.broadcast.sub**  
*Returns element-wise difference of the input arrays with broadcasting.*

**Description**

'broadcast_minus' is an alias to the function 'broadcast_sub'.

**Arguments**

- **lhs**  
  NDArray-or-Symbol First input to the function

- **rhs**  
  NDArray-or-Symbol Second input to the function

**Details**

Example::

```python
x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]
broadcast_sub(x, y) = [[ 1., 1., 1.], [ 0., 0., 0.]]
broadcast_minus(x, y) = [[ 1., 1., 1.], [ 0., 0., 0.]]
```

Supported sparse operations:

- `broadcast_sub/minus(csr, dense(1D)) = dense broadcast_sub/minus(dense(1D), csr) = dense`

Defined in `src/operator/tensor/elemwise_binary_broadcast_op_basic.cc:L106`

**Value**

- **out** The result mx.ndarray

---

**mx.nd.broadcast.to**  
*Broadcasts the input array to a new shape.*

**Description**

Broadcasting is a mechanism that allows NDArrays to perform arithmetic operations with arrays of different shapes efficiently without creating multiple copies of arrays. Also see, ‘Broadcasting’ for more explanation.

**Arguments**

- **data**  
  NDArray-or-Symbol The input

- **shape**  
  Shape(tuple), optional, default=[]) The shape of the desired array. We can set the dim to zero if it’s same as the original. E.g `A = broadcast_to(B, shape=(10, 0, 0))` has the same meaning as `A = broadcast_axis(B, axis=0, size=10)`.
mx.nd.Cast

Details

Broadcasting is allowed on axes with size 1, such as from `(2,1,3,1)` to `(2,8,3,9)`. Elements will be duplicated on the broadcasted axes.

For example:

```python
cast_to([[1,2,3]], shape=(2,3)) = [[1., 2., 3.], [1., 2., 3.]]
```

The dimension which you do not want to change can also be kept as ‘0’ which means copy the original value. So with `shape=(2,0)`, we will obtain the same result as in the above example.

Defined in src/operator/tensor/broadcast_reduce_op_value.cc:L117

Value

- `out` The result mx.nd.array

mx.nd.Cast

Casts all elements of the input to a new type.

Description

.. note:: “Cast” is deprecated. Use “cast” instead.

Arguments

- **data** NDArray-or-Symbol The input.
- **dtype** 'bfloat16', 'bool', 'float16', 'float32', 'int32', 'int64', 'int8', 'uint8', required Output data type.

Details

Example:

```python
cast([0.9, 1.3], dtype='int32') = [0, 1] cast([1e20, 11.1], dtype='float16') = [inf, 11.09375] cast([300, 11.1, 10.9, -1, -3], dtype='uint8') = [44, 11, 10, 255, 253]
```

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L664

Value

- `out` The result mx.nd.array
**mx.nd.cast**

**Casts all elements of the input to a new type.**

**Description**

.. note:: “Cast” is deprecated. Use “cast” instead.

**Arguments**

- **data**
  - NDArray-or-Symbol The input.
- **dtype**
  - 'bfloat16', 'bool', 'float16', 'float32', 'float64', 'int32', 'int64', 'int8', 'uint8', required Output data type.

**Details**

Example::

    cast([0.9, 1.3], dtype='int32') = [0, 1]  
    cast([1e20, 11.1], dtype='float16') = [inf, 11.09375]  
    cast([300, 11.1, 10.9, -1, -3], dtype='uint8') = [44, 11, 10, 255, 253]

Defined in `src/operator/tensor/elemwise_unary_op_basic.cc:L664`

**Value**

- **out** The result mx.ndarray

---

**mx.nd.cast.storage**

**Casts tensor storage type to the new type.**

**Description**

When an NDArray with default storage type is cast to csr or row_sparse storage, the result is compact, which means:

**Arguments**

- **data**
  - NDArray-or-Symbol The input.
- **stype**
  - 'csr', 'default', 'row_sparse', required Output storage type.
Details
- for csr, zero values will not be retained - for row_sparse, row slices of all zeros will not be retained

The storage type of “cast_storage“ output depends on stype parameter:
- cast_storage(csr, 'default') = default - cast_storage(row_sparse, 'default') = default - cast_storage(default, 'csr') = csr - cast_storage(default, 'row_sparse') = row_sparse - cast_storage(csr, 'csr') = csr - cast_storage(row_sparse, 'row_sparse') = row_sparse

Example::

dense = [[ 0., 1., 0.], [ 2., 0., 3.], [ 0., 0., 0.], [ 0., 0., 0.]]
# cast to row_sparse storage type rsp = cast_storage(dense, 'row_sparse') rsp.indices = [0, 1]
# cast to csr storage type csr = cast_storage(dense, 'csr') csr.indices = [1, 0, 2] csr.values = [1., 2., 3.]

Defined in src/operator/tensor/cast_storage.cc:L71

Value
out The result mx.ndarray

mx.nd.cbrt

Returns element-wise cube-root value of the input.

Description
.. math:: cbrt(x) = \sqrt[3]{x}

Arguments

data NDArray-or-Symbol The input array.

Details

Example::
cbrt([1, 8, -125]) = [1, 2, -5]

The storage type of “cbrt“ output depends upon the input storage type:
- cbrt(default) = default - cbrt(row_sparse) = row_sparse - cbrt(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_pow.cc:L270

Value
out The result mx.ndarray
mx.nd.ceil

Returns element-wise ceiling of the input.

Description

The ceil of the scalar x is the smallest integer i, such that i >= x.

Arguments

data

NDArray-or-Symbol The input array.

Details

Example::

    ceil([-2.1, -1.9, 1.5, 1.9, 2.1]) = [-2., -1., 2., 2., 3.]

The storage type of "ceil" output depends upon the input storage type:
- ceil(default) = default - ceil(row_sparse) = row_sparse - ceil(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L817

Value

out The result mx.ndarray

mx.nd.choose.element.0index

Picks elements from an input array according to the input indices along the given axis.

Description

Given an input array of shape "(d0, d1)" and indices of shape "(i0,)", the result will be an output array of shape "(i0,)" with::

Arguments

data

NDArray-or-Symbol The input array

index

NDArray-or-Symbol The index array

axis

int or None, optional, default=-1’ int or None. The axis to picking the elements. Negative values means indexing from right to left. If is ‘None’, the elements in the index w.r.t the flattened input will be picked.

keepdims

boolean, optional, default=0 If true, the axis where we pick the elements is left in the result as dimension with size one.

mode

‘clip’, ‘wrap’,optional, default=’clip’ Specify how out-of-bound indices behave. Default is "clip". "clip" means clip to the range. So, if all indices mentioned are too large, they are replaced by the index that addresses the last element along an axis. "wrap" means to wrap around.
Details

output[i] = input[i, indices[i]]

By default, if any index mentioned is too large, it is replaced by the index that addresses the last element along an axis (the ‘clip’ mode).

This function supports n-dimensional input and (n-1)-dimensional indices arrays.

Examples::

x = [[ 1., 2.], [ 3., 4.], [ 5., 6.]]
// picks elements with specified indices along axis 0 pick(x, y=[0,1], 0) = [ 1., 4.]
// picks elements with specified indices along axis 1 pick(x, y=[0,1,0], 1) = [ 1., 4., 5.]
// picks elements with specified indices along axis 1 using 'wrap' mode // to place indicies that
// would normally be out of bounds pick(x, y=[2,-1,-2], 1, mode='wrap') = [ 1., 4., 5.]
y = [[ 1.], [ 0.], [ 2.]]
// picks elements with specified indices along axis 1 and dims are maintained pick(x, y, 1, keep-
dims=True) = [[ 2.], [ 3.], [ 6.]]

Defined in src/operator/tensor/broadcast_reduce_op_index.cc:L151

Value

out The result mx.nd.array

mx.nd.clip

Clips (limits) the values in an array. Given an interval, values outside the interval are clipped to the interval edges. Clipping “x” between ‘a_min’ and ‘a_max’ would be: .. math:: clip(x, a\_min, a\_max) = \\max(\\min(x, a\_max), a\_min))

Example:: x = [0, 1, 2, 3, 4, 5, 6, 7, 8, 9] clip(x,1,8) = [ 1., 1., 2., 3., 4., 5., 6., 7., 8., 8.]

The storage type of “clip” output depends on storage types of inputs and the a_min, a_max parameter values: - clip(default) = default - clip(row_sparse, a_min <= 0, a_max >= 0) = row_sparse - clip(csr, a_min <= 0, a_max >= 0) = csr - clip(row_sparse, a_min < 0, a_max <= 0) = default - clip(row_sparse, a_min < 0, a_max < 0) = default - clip(csr, a_min < 0, a_max < 0) = csr - clip(csr, a_min > 0, a_max > 0) = csr

Description

Defined in src/operator/tensor/matrix_op.cc:L677

Arguments

data NDArray-or-Symbol Input array.
a.min float, required Minimum value
a.max float, required Maximum value
mx.nd.col2im

Combining the output column matrix of im2col back to image array.

Description

Like :class:`~mxnet.ndarray.im2col`, this operator is also used in the vanilla convolution implementation. Despite the name, col2im is not the reverse operation of im2col. Since there may be overlaps between neighbouring sliding blocks, the column elements cannot be directly put back into image. Instead, they are accumulated (i.e., summed) in the input image just like the gradient computation, so col2im is the gradient of im2col and vice versa.

Arguments

- **data**
  NDArray-or-Symbol Input array to combine sliding blocks.
- **output.size**
  Shape(tuple), required The spatial dimension of image array: (w,), (h, w) or (d, h, w).
- **kernel**
  Shape(tuple), required Sliding kernel size: (w,), (h, w) or (d, h, w).
- **stride**
  Shape(tuple), optional, default=[]) The stride between adjacent sliding blocks in spatial dimension: (w,), (h, w) or (d, h, w). Defaults to 1 for each dimension.
- **dilate**
  Shape(tuple), optional, default=[]) The spacing between adjacent kernel points: (w,), (h, w) or (d, h, w). Defaults to 1 for each dimension.
- **pad**
  Shape(tuple), optional, default=[]) The zero-value padding size on both sides of spatial dimension: (w,), (h, w) or (d, h, w). Defaults to no padding.

Details

Using the notation in im2col, given an input column array of shape :math:`(N, C \times \prod(\text{kernel}), W)`; this operator accumulates the column elements into output array of shape :math:`(N, C, \text{output_size}[0], \text{output_size}[1], \ldots)`. Only 1-D, 2-D and 3-D of spatial dimension is supported in this operator.

Defined in src/operator/nn/im2col.cc:L182

Value

- **out** The result mx.ndarray
**mx.nd.concat**

Joins input arrays along a given axis.

**Description**

.. note:: ‘Concat’ is deprecated. Use ‘concat’ instead.

**Arguments**

- **data**
  NDArray-or-Symbol[] List of arrays to concatenate
- **num.arg**
  int, required Number of inputs to be concated.
- **dim**
  int, optional, default=’1’ the dimension to be concated.

**Details**

The dimensions of the input arrays should be the same except the axis along which they will be concatenated. The dimension of the output array along the concatenated axis will be equal to the sum of the corresponding dimensions of the input arrays.

The storage type of “concat” output depends on storage types of inputs

- concat(csr, csr, ..., csr, dim=0) = csr - otherwise, “concat” generates output with default storage

**Example::**

```python
x = [[1,1],[2,2]] y = [[3,3],[4,4],[5,5]] z = [[6,6],[7,7],[8,8]]
concat(x,y,z,dim=0) = [[ 1., 1.], [ 2., 2.], [ 3., 3.], [ 4., 4.], [ 5., 5.], [ 6., 6.], [ 7., 7.], [ 8., 8.]]
```

Note that you cannot concat x,y,z along dimension 1 since dimension 0 is not the same for all the input arrays.

```python
concat(y,z,dim=1) = [[ 3., 3., 6., 6.], [ 4., 4., 7., 7.], [ 5., 5., 8., 8.]]
```

Defined in src/operator/nn/concat.cc:L385

**Value**

- **out** The result mx.ndarray

---

**mx.nd.concat**

Joins input arrays along a given axis.

**Description**

.. note:: ‘Concat’ is deprecated. Use ‘concat’ instead.
mx.nd.Convolution

Compute *N*-D convolution on *(N+2)*-D input.

Description
In the 2-D convolution, given input data with shape *(batch_size, channel, height, width)*, the output is computed by

Arguments

data NDArray-or-Symbol Input data to the ConvolutionOp.
weight NDArray-or-Symbol Weight matrix.
bias NDArray-or-Symbol Bias parameter.
kernel Shape(tuple), required Convolution kernel size: (w,), (h, w) or (d, h, w)
stride Shape(tuple), optional, default=[] Convolution stride: (w,), (h, w) or (d, h, w). Defaults to 1 for each dimension.
dilate Shape(tuple), optional, default=[] Convolution dilate: (w,), (h, w) or (d, h, w). Defaults to 1 for each dimension.
mx.nd.Convolution

**pad**
Shape(tuple), optional, default=[] Zero pad for convolution: (w,), (h, w) or (d, h, w). Defaults to no padding.

**num.filter**
int (non-negative), required Convolution filter(channel) number

**num.group**
int (non-negative), optional, default=1 Number of group partitions.

**workspace**
long (non-negative), optional, default=1024 Maximum temporary workspace allowed (MB) in convolution. This parameter has two usages. When CUDNN is not used, it determines the effective batch size of the convolution kernel. When CUDNN is used, it controls the maximum temporary storage used for tuning the best CUDNN kernel when ‘limited_workspace’ strategy is used.

**no.bias**
boolean, optional, default=0 Whether to disable bias parameter.

**cudnn.tune**

**cudnn.off**
boolean, optional, default=0 Turn off cudnn for this layer.

**layout**
None, ‘NCDHW’, ‘NCHW’, ‘NCW’, ‘NDHWC’, ‘NHWC’, optional, default=’None’ Set layout for input, output and weight. Empty for default layout: NCW for 1d, NCHW for 2d and NCDHW for 3d. NHWC and NDHWC are only supported on GPU.

**Details**

.. math::
\text{out}[n,i,:,:] = \text{bias}[i] + \sum_j=0^\text{channel} \text{data}[n,j,:,:] \star \text{weight}[i,j,:,:]

where :math:`\star` is the 2-D cross-correlation operator.

For general 2-D convolution, the shapes are

- **data**: *(batch_size, channel, height, width)*
- **weight**: *(num_filter, channel, kernel[0], kernel[1])*  
- **bias**: *(num_filter,)*
- **out**: *(batch_size, num_filter, out_height, out_width)*

Define:

\[ f(x,k,p,s,d) = \text{floor}(x+2*p-d*(k-1)-1)/s)+1 \]

then we have:

\[ \text{out}_{height}=f(\text{height}, \text{kernel}[0], \text{pad}[0], \text{stride}[0], \text{dilate}[0]) \]
\[ \text{out}_{width}=f(\text{width}, \text{kernel}[1], \text{pad}[1], \text{stride}[1], \text{dilate}[1]) \]

If “no.bias” is set to be true, then the “bias” term is ignored.

The default data “layout” is *NCHW*, namely *(batch_size, channel, height, width)*. We can choose other layouts such as *NWC*.

If “num_group” is larger than 1, denoted by *g*, then split the input “data” evenly into *g* parts along the channel axis, and also evenly split “weight” along the first dimension. Next compute the convolution on the *i*-th part of the data with the *i*-th weight part. The output is obtained by concatenating all the *g* results.

1-D convolution does not have *height* dimension but only *width* in space.

- **data**: *(batch_size, channel, width)*  
- **weight**: *(num_filter, channel, kernel[0])*  
- **bias**: *(num_filter,)*  
- **out**: *(batch_size, num_filter, out_width)*.
3-D convolution adds an additional *depth* dimension besides *height* and *width*. The shapes are:

- **data**: *(batch_size, channel, depth, height, width)*
- **weight**: *(num_filter, channel, kernel[0], kernel[1], kernel[2])*  
- **bias**: *(num_filter,)*
- **out**: *(batch_size, num_filter, out_depth, out_height, out_width)*.

Both “weight” and “bias” are learnable parameters.

There are other options to tune the performance:

- **cudnn_tune**: enable this option leads to higher startup time but may give faster speed. Options are  
  - **off**: no tuning  
  - **limited_workspace**: run test and pick the fastest algorithm that doesn’t exceed workspace limit.  
  - **fastest**: pick the fastest algorithm and ignore workspace limit.  
  - **None** (default): the behavior is determined by environment variable “MXNET_CUDNN_AUTOTUNE_DEFAULT”.  
    0 for off, 1 for limited workspace (default), 2 for fastest.

- **workspace**: A large number leads to more (GPU) memory usage but may improve the performance.

Defined in `src/operator/nn/convolution.cc:L476`

**Value**

out The result mx.ndarray

---

**mx.nd.Convolution.v1**  
This operator is DEPRECATED. Apply convolution to input then add a bias.

**Description**

This operator is DEPRECATED. Apply convolution to input then add a bias.

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>NDArray-or-Symbol Input data to the ConvolutionV1Op.</td>
</tr>
<tr>
<td>weight</td>
<td>NDArray-or-Symbol Weight matrix.</td>
</tr>
<tr>
<td>bias</td>
<td>NDArray-or-Symbol Bias parameter.</td>
</tr>
<tr>
<td>kernel</td>
<td>Shape(tuple), required convolution kernel size: (h, w) or (d, h, w)</td>
</tr>
<tr>
<td>stride</td>
<td>Shape(tuple), optional, default=[] convolution stride: (h, w) or (d, h, w)</td>

</tr>
</tbody>
</table>
workspace long (non-negative), optional, default=1024 Maximum temporary workspace allowed for convolution (MB). This parameter determines the effective batch size of the convolution kernel, which may be smaller than the given batch size. Also, the workspace will be automatically enlarged to make sure that we can run the kernel with batch_size=1

no.bias boolean, optional, default=0 Whether to disable bias parameter.

cudnn.tune None, 'fastest', 'limited_workspace', 'off', optional, default='None' Whether to pick convolution algo by running performance test. Leads to higher startup time but may give faster speed. Options are: 'off': no tuning 'limited_workspace': run test and pick the fastest algorithm that doesn't exceed workspace limit. 'fastest': pick the fastest algorithm and ignore workspace limit. If set to None (default), behavior is determined by environment variable MXNET_CUDNN_AUTOTUNE_DEFAULT: 0 for off, 1 for limited workspace (default), 2 for fastest.

cudnn.off boolean, optional, default=0 Turn off cudnn for this layer.

layout None, 'NCDHW', 'NCHW', 'NDHWC', 'NHWC', optional, default='None' Set layout for input, output and weight. Empty for default layout: NCHW for 2d and NCDHW for 3d.

Value

out The result mx.ndarray

mx.nd.copyto Generate an mx.ndarray object on ctx, with data copied from src

Description

Generate an mx.ndarray object on ctx, with data copied from src

Usage

mx.nd.copyto(src, ctx)

Arguments

src The source mx.ndarray object.

ctx The target context.
The correlation layer performs multiplicative patch comparisons between two feature maps.

**Arguments**

- **data1**: NDArray-or-Symbol. Input data1 to the correlation.
- **data2**: NDArray-or-Symbol. Input data2 to the correlation.
- **kernel.size**: int (non-negative), optional, default=1. Kernel size for Correlation must be an odd number.
- **max.displacement**: int (non-negative), optional, default=1. Max displacement of Correlation.
- **stride1**: int (non-negative), optional, default=1. Stride1 quantize data1 globally.
- **stride2**: int (non-negative), optional, default=1. Stride2 quantize data2 within the neighborhood centered around data1.
- **pad.size**: int (non-negative), optional, default=0. Pad for Correlation.
- **is.multiply**: boolean, optional, default=1. Operation type is either multiplication or subduction.

**Details**

Given two multi-channel feature maps :math:`f_1, f_2`, with :math:`w`, :math:`h`, and :math:`c` being their width, height, and number of channels, the correlation layer lets the network compare each patch from :math:`f_1` with each patch from :math:`f_2`.

For now we consider only a single comparison of two patches. The ‘correlation’ of two patches centered at :math:`x_1` in the first map and :math:`x_2` in the second map is then defined as:

.. math::
   c(x_1, x_2) = \sum_{o \in [-k,k] \times [-k,k]} \langle f_1(x_1 + o), f_2(x_2 + o) \rangle

for a square patch of size :math:`K := 2k + 1`.

Note that the equation above is identical to one step of a convolution in neural networks, but instead of convolving data with a filter, it convolves data with other data. For this reason, it has no training weights.

Computing :math:`c(x_1, x_2)` involves :math:`c * K^2` multiplications. Comparing all patch combinations involves :math:`w^2 h^2 K^2` such computations.

Given a maximum displacement :math:`d`, for each location :math:`x_1` it computes correlations :math:`c(x_1, x_2)` only in a neighborhood of size :math:`D := 2d + 1`, by limiting the range of :math:`x_2`. We use strides :math:`s_1, s_2`, to quantize :math:`x_1` globally and to quantize :math:`x_2` within the neighborhood centered around :math:`x_1`.

The final output is defined by the following expression:

.. math::
   out[n, q, i, j] = c(x_i, j, x_q)
where $i$ and $j$ enumerate spatial locations in $f_1$, and $q$ denotes the $q^{th}$ neighborhood of $x_{ij}$.

Defined in src/operator/correlation.cc:L198

**Value**

out The result mx.ndarray

---

### mx.nd.cos

**Computes the element-wise cosine of the input array.**

**Description**

The input should be in radians ($2\pi$ rad equals 360 degrees).

**Arguments**

- data NDArray-or-Symbol The input array.

**Details**

.. math:: \cos([0, \pi/4, \pi/2]) = [1, 0.707, 0]

The storage type of “cos” output is always dense

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L90

**Value**

out The result mx.ndarray

---

### mx.nd.cosh

**Returns the hyperbolic cosine of the input array, computed element-wise.**

**Description**

.. math:: \cosh(x) = 0.5 \times (\exp(x) + \exp(-x))

**Arguments**

- data NDArray-or-Symbol The input array.

**Details**

The storage type of “cosh” output is always dense

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L409
**mx.nd.Crop**

**Value**

out The result mx.ndarray

```markdown
mx.nd.Crop

.. note:: ‘Crop’ is deprecated. Use ‘slice’ instead.
```

**Description**

Crop the 2nd and 3rd dim of input data, with the corresponding size of h_w or with width and height of the second input symbol, i.e., with one input, we need h_w to specify the crop height and width, otherwise the second input symbol’s size will be used.

**Arguments**

- **data**: Symbol or Symbol[] Tensor or List of Tensors, the second input will be used as crop_like shape reference
- **num.args**: int, required Number of inputs for crop, if equals one, then we will use the h_w for crop height and width, else if equals two, then we will use the height and width of the second input symbol, we name crop_like here
- **offset**: Shape(tuple), optional, default=[0,0] crop offset coordinate: (y, x)
- **h.w**: Shape(tuple), optional, default=[0,0] crop height and width: (h, w)
- **center.crop**: boolean, optional, default=0 If set to true, then it will use be the center_crop, or it will crop using the shape of crop_like

**Details**

Defined in src/operator/crop.cc:L50

**Value**

out The result mx.ndarray
mx.nd.crop

Slices a region of the array. note:: “crop” is deprecated. Use “slice” instead. This function returns a sliced array between the indices given by ‘begin’ and ‘end’ with the corresponding ‘step’. For an input array of “shape=(d_0, d_1, ..., d_n-1)”, slice operation with “begin=(b_0, b_1...b_m-1)” , “end=(e_0, e_1, ..., e_m-1)”, and “step=(s_0, s_1, ..., s_m-1)”, where m <= n, results in an array with the shape “(|e_0-b_0|/|s_0|, ..., |e_m-1-b_m-1|/|s_m-1|, d_m, ..., d_n-1)”. The resulting array’s *k*-th dimension contains elements from the *k*-th dimension of the input array starting from index “b_k” (inclusive) with step “s_k” until reaching “e_k” (exclusive). If the *k*-th elements are ‘None’ in the sequence of ‘begin’, ‘end’, and ‘step’, the following rule will be used to set default values. If ‘s_k’ is ‘None’, set ‘s_k=1’. If ‘s_k > 0’, set ‘b_k=0’, ‘e_k=d_k’; else, set ‘b_k=d_k-1’, ‘e_k=-1’. The storage type of “slice” output depends on storage types of inputs - slice(csr) = csr - otherwise, “slice” generates output with default storage .. note:: When input data storage type is csr, it only supports step=(), or step=(None,), or step=(1,) to generate a csr output. For other step parameter values, it falls back to slicing a dense tensor. Example:: x = [[ 1., 2., 3., 4.], [ 5., 6., 7., 8.], [ 9., 10., 11., 12.]] slice(x, begin=(0,1), end=(2,4)) = [[ 2., 3., 4.], [ 6., 7., 8.]] slice(x, begin=(None, 0), end=(None, 3), step=(-1, 2)) = [[9., 11., 13.], [5., 7.], [1., 3.]]

Description

Defined in src/operator/tensor/matrix_op.cc:L482

Arguments

data NDArray-or-Symbol Source input

begin Shape(tuple), required starting indices for the slice operation, supports negative indices.

end Shape(tuple), required ending indices for the slice operation, supports negative indices.

step Shape(tuple), optional, default=[] step for the slice operation, supports negative values.

Value

out The result mx.ndarray
Description

.. note:: The existing alias “contrib_CTCLoss” is deprecated.

Arguments

data : NDArray-or-Symbol
Input ndarray

label : NDArray-or-Symbol
Ground-truth labels for the loss.

data.lengths : NDArray-or-Symbol
Lengths of data for each of the samples. Only required when use_data_lengths is true.

label.lengths : NDArray-or-Symbol
Lengths of labels for each of the samples. Only required when use_label_lengths is true.

use.data.lengths : boolean, optional, default=0
Whether the data lengths are decided by ‘data_lengths’. If false, the lengths are equal to the max sequence length.

use.label.lengths : boolean, optional, default=0
Whether the label lengths are decided by ‘label_lengths’, or derived from ‘padding_mask’. If false, the lengths are derived from the first occurrence of the value of ‘padding_mask’. The value of ‘padding_mask’ is “0” when first CTC label is reserved for blank, and “-1” when last label is reserved for blank. See ‘blank_label’.

blank.label : ‘first’, ‘last’, optional, default=’first’
Set the label that is reserved for blank label. If “first”, 0-th label is reserved, and label values for tokens in the vocabulary are between “1” and “alphabet_size-1”, and the padding mask is “-1”. If “last”, last label value “alphabet_size-1” is reserved for blank label instead, and label values for tokens in the vocabulary are between “0” and “alphabet_size-2”, and the padding mask is “0”.

Details

The shapes of the inputs and outputs:

- **data**: `(sequence_length, batch_size, alphabet_size)`
- **label**: `(batch_size, label_sequence_length)`
- **out**: `(batch_size)`

The ‘data’ tensor consists of sequences of activation vectors (without applying softmax), with i-th channel in the last dimension corresponding to i-th label for i between 0 and alphabet_size-1 (i.e always 0-indexed). Alphabet size should include one additional value reserved for blank label. When ‘blank_label’ is “‘first’”, the “0”-th channel is be reserved for activation of blank label, or otherwise if it is "last", “(alphabet_size-1)"-th channel should be reserved for blank label.

“label” is an index matrix of integers. When ‘blank_label’ is “‘first’”, the value 0 is then reserved for blank label, and should not be passed in this matrix. Otherwise, when ‘blank_label’ is “‘last’", the value ‘(alphabet_size-1)’ is reserved for blank label.
If a sequence of labels is shorter than *label_sequence_length*, use the special padding value at the end of the sequence to conform it to the correct length. The padding value is '0' when 'blank_label' is ‘"first"’, and ‘-1’ otherwise.

For example, suppose the vocabulary is ‘[a, b, c]’, and in one batch we have three sequences 'ba', 'cbb', and 'abac'. When 'blank_label' is ‘"first"’, we can index the labels as ‘‘a’: 1, ‘b’: 2, ‘c’: 3’, and we reserve the 0-th channel for blank label in data tensor. The resulting ‘label’ tensor should be padded to be:

```
[[2, 1, 0, 0], [3, 2, 2, 0], [1, 2, 1, 3]]
```

When 'blank_label' is ‘"last"’, we can index the labels as ‘‘a’: 0, ‘b’: 1, ‘c’: 2’, and we reserve the channel index 3 for blank label in data tensor. The resulting 'label' tensor should be padded to be:

```
[[1, 0, -1, -1], [2, 1, 1, -1], [0, 1, 0, 2]]
```

“out” is a list of CTC loss values, one per example in the batch.

See *Connectionist Temporal Classification: Labelling Unsegmented Sequence Data with Recurrent Neural Networks*, A. Graves *et al*. for more information on the definition and the algorithm.

Defined in src/operator/nn/ctc_loss.cc:L100

**Value**

out The result mx.ndarray

---

mx.nd.CTCLoss  
Connectionist Temporal Classification Loss.

**Description**

.. note:: The existing alias “contrib_CTCLoss” is deprecated.

**Arguments**

- **data**: NDArray-or-Symbol Input ndarray
- **label**: NDArray-or-Symbol Ground-truth labels for the loss.
- **data.lengths**: NDArray-or-Symbol Lengths of data for each of the samples. Only required when use_data_lengths is true.
- **label.lengths**: NDArray-or-Symbol Lengths of labels for each of the samples. Only required when use_label_lengths is true.
- **use.data.lengths**: boolean, optional, default=0 Whether the data lenghts are decided by 'data_lengths'. If false, the lengths are equal to the max sequence length.
- **use.label.lengths**: boolean, optional, default=0 Whether the label lengths are decided by 'label_lengths', or derived from 'padding_mask'. If false, the lengths are derived from the first occurrence of the value of 'padding_mask'. The value of 'padding_mask' is “0” when first CTC label is reserved for blank, and “-1” when last label is reserved for blank. See ‘blank_label’.
mx.nd.CTCLoss

blank.label 'first', 'last', optional, default='first' Set the label that is reserved for blank label. If 'first', 0-th label is reserved, and label values for tokens in the vocabulary are between "1" and "alphabet_size-1", and the padding mask is "-1". If 'last', last label value "alphabet_size-1" is reserved for blank label instead, and label values for tokens in the vocabulary are between "0" and "alphabet_size-2", and the padding mask is "0".

Details

The shapes of the inputs and outputs:
- **data**: '(sequence_length, batch_size, alphabet_size)' - **label**: '(batch_size, label_sequence_length)' - **out**: '(batch_size)'

The 'data' tensor consists of sequences of activation vectors (without applying softmax), with i-th channel in the last dimension corresponding to i-th label for i between 0 and alphabet_size-1 (i.e always 0-indexed). Alphabet size should include one additional value reserved for blank label. When 'blank_label' is "first", the "0"-th channel is reserved for activation of blank label, or otherwise if it is "last", "(alphabet_size-1)"-th channel should be reserved for blank label.

"label" is an index matrix of integers. When 'blank_label' is "first", the value 0 is then reserved for blank label, and should not be passed in this matrix. Otherwise, when 'blank_label' is "last", the value "(alphabet_size-1)" is reserved for blank label.

If a sequence of labels is shorter than *label_sequence_length*, use the special padding value at the end of the sequence to conform it to the correct length. The padding value is '0' when 'blank_label' is "first", and '-1' otherwise.

For example, suppose the vocabulary is '[a, b, c]', and in one batch we have three sequences 'ba', 'cbb', and 'abac'. When 'blank_label' is "first", we can index the labels as 'a': 1, 'b': 2, 'c': 3, and we reserve the 0-th channel for blank label in data tensor. The resulting 'label' tensor should be padded to be::

\[
[[2, 1, 0, 0], [3, 2, 2, 0], [1, 2, 1, 3]]
\]

When 'blank_label' is "last", we can index the labels as 'a': 0, 'b': 1, 'c': 2, and we reserve the 0-th channel for blank label in data tensor. The resulting 'label' tensor should be padded to be::

\[
[[1, 0, -1, -1], [2, 1, 1, -1], [0, 1, 0, 2]]
\]

"out" is a list of CTC loss values, one per example in the batch.

See *Connectionist Temporal Classification: Labelling Unsegmented Sequence Data with Recurrent Neural Networks*, A. Graves *et al*. for more information on the definition and the algorithm.

Defined in src/operator/nn/ctc_loss.cc:L100

Value

out The result mx.ndarray
mx.nd.cumsum

Return the cumulative sum of the elements along a given axis.

Description
Defined in src/operator/numpy/np_cumsum.cc:L70

Arguments
- **a**: NDArray-or-Symbol Input ndarray
- **axis**: int or None, optional, default='None' Axis along which the cumulative sum is computed. The default (None) is to compute the cumsum over the flattened array.
- **dtype**: None, 'float16', 'float32', 'float64', 'int32', 'int64', 'int8', optional, default='None' Type of the returned array and of the accumulator in which the elements are summed. If dtype is not specified, it defaults to the dtype of a, unless a has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

Value
- **out**: The result mx.ndarray

mx.nd.Custom

Apply a custom operator implemented in a frontend language (like Python).

Description
Custom operators should override required methods like ‘forward’ and ‘backward’. The custom operator must be registered before it can be used. Please check the tutorial here: https://mxnet.incubator.apache.org/api/faq/new_op

Arguments
- **data**: NDArray-or-Symbol[] Input data for the custom operator.
- **op.type**: string Name of the custom operator. This is the name that is passed to ‘mx.operator.register’ to register the operator.

Details
Defined in src/operator/custom/custom.cc:L547

Value
- **out**: The result mx.ndarray
mx.nd.Deconvolution

Computes 1D or 2D transposed convolution (aka fractionally strided convolution) of the input tensor. This operation can be seen as the gradient of Convolution operation with respect to its input. Convolution usually reduces the size of the input. Transposed convolution works the other way, going from a smaller input to a larger output while preserving the connectivity pattern.

Description
Computes 1D or 2D transposed convolution (aka fractionally strided convolution) of the input tensor. This operation can be seen as the gradient of Convolution operation with respect to its input. Convolution usually reduces the size of the input. Transposed convolution works the other way, going from a smaller input to a larger output while preserving the connectivity pattern.

Arguments

data: NDArray-or-Symbol Input tensor to the deconvolution operation.
weight: NDArray-or-Symbol Weights representing the kernel.
bias: NDArray-or-Symbol Bias added to the result after the deconvolution operation.
kernel: Shape(tuple), required Deconvolution kernel size: (w,), (h, w) or (d, h, w). This is same as the kernel size used for the corresponding convolution
stride: Shape(tuple), optional, default=[] The stride used for the corresponding convolution: (w,), (h, w) or (d, h, w). Defaults to 1 for each dimension.
dilate: Shape(tuple), optional, default=[] Dilation factor for each dimension of the input: (w,), (h, w) or (d, h, w). Defaults to 1 for each dimension.
pad: Shape(tuple), optional, default=[] The amount of implicit zero padding added during convolution for each dimension of the input: (w,), (h, w) or (d, h, w). “(kernel-1)/2” is usually a good choice. If ‘target_shape’ is set, ‘pad’ will be ignored and a padding that will generate the target shape will be used. Defaults to no padding.
adj: Shape(tuple), optional, default=[] Adjustment for output shape: (w,), (h, w) or (d, h, w). If ‘target_shape’ is set, ‘adj’ will be ignored and computed accordingly.
target_shape: Shape(tuple), optional, default=[] Shape of the output tensor: (w,), (h, w) or (d, h, w).
num.filter: int (non-negative), required Number of output filters.
num.group: int (non-negative), optional, default=1 Number of groups partition.
workspace: long (non-negative), optional, default=512 Maximum temporary workspace allowed (MB) in deconvolution. This parameter has two usages. When CUDNN is not used, it determines the effective batch size of the deconvolution kernel. When CUDNN is used, it controls the maximum temporary storage used for tuning the best CUDNN kernel when ‘limited_workspace’ strategy is used.
no.bias: boolean, optional, default=1 Whether to disable bias parameter.
cudnn.off: boolean, optional, default=0 Turn off cudnn for this layer.
layout: None, 'NCDHW', 'NCHW', 'NCW', 'NDHWC', 'NHWC'.optional, default=’None’ Set layout for input, output and weight. Empty for default layout, NCW for 1d, NCHW for 2d and NCDHW for 3d. NHWC and NDHWC are only supported on GPU.

Value

out: The result mx.ndarray

mx.nd.degrees

Converting each element of the input array from radians to degrees.

Description

.. math:: degrees([0, \pi/2, \pi, 3\pi/2, 2\pi]) = [0, 90, 180, 270, 360]

Arguments

data: NDArray-or-Symbol The input array.

Details

The storage type of “degrees“ output depends upon the input storage type:
- degrees(default) = default - degrees(row_sparse) = row_sparse - degrees(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L332

Value

out: The result mx.ndarray
mx.nd.depth.to.space

Rearranges (permutes) data from depth into blocks of spatial data. Similar to ONNX DepthToSpace operator: https://github.com/onnx/onnx/blob/master/docs/Operators.md#DepthToSpace. The output is a new tensor where the values from depth dimension are moved in spatial blocks to height and width dimension. The reverse of this operation is “space_to_depth”. .. math:: \begin{align*}
x' &= \text{reshape}(x, [N, \text{block}_\text{size}, \text{block}_\text{size}, C / (\text{block}_\text{size}^2), H \times \text{block}_\text{size}, W \times \text{block}_\text{size}]) \\
x'' &= \text{transpose}(x', [0, 3, 4, 1, 5, 2]) \\
y &= \text{reshape}(x'', [N, C / (\text{block}_\text{size}^2), H \times \text{block}_\text{size}, W \times \text{block}_\text{size}])
\end{align*}

where :math:`x` is an input tensor with default layout as :math:`[N, C, H, W]`:
[batch, channels, height, width] and :math:`y` is the output tensor of layout:
math:`[N, C / (\text{block}_\text{size}^2), H \times \text{block}_\text{size}, W \times \text{block}_\text{size}]`

Example:

\[
x = \begin{bmatrix}
[0, 1, 2], [3, 4, 5] \\
[6, 7, 8], [9, 10, 11] \\
[12, 13, 14], [15, 16, 17] \\
[18, 19, 20], [21, 22, 23]
\end{bmatrix}
\]

\[
\text{depth_to_space}(x, 2) = \begin{bmatrix}
[0, 6, 1, 7, 2, 8] \\
[12, 18, 13, 19, 14, 20] \\
[3, 9, 4, 10, 5, 11] \\
[15, 21, 16, 22, 17, 23]
\end{bmatrix}
\]

Description

Defined in src/operator/tensor/matrix_op.cc:L972

Arguments

- **data**: NDArray-or-Symbol Input ndarray
- **block.size**: int, required Blocks of [block.size, block.size] are moved

Value

- **out**: The result mx.ndarray

mx.nd.diag

Extracts a diagonal or constructs a diagonal array.

Description

“diag”'s behavior depends on the input array dimensions:

Arguments

- **data**: NDArray-or-Symbol Input ndarray
- **k**: int, optional, default=’0’ Diagonal in question. The default is 0. Use k>0 for diagonals above the main diagonal, and k<0 for diagonals below the main diagonal. If input has shape (S0 S1) k must be between -S0 and S1
axis1 : int, optional, default=’0’ The first axis of the sub-arrays of interest. Ignored when the input is a 1-D array.

axis2 : int, optional, default=’1’ The second axis of the sub-arrays of interest. Ignored when the input is a 1-D array.

Details

- 1-D arrays: constructs a 2-D array with the input as its diagonal, all other elements are zero. - N-D arrays: extracts the diagonals of the sub-arrays with axes specified by “axis1” and “axis2”. The output shape would be decided by removing the axes numbered “axis1” and “axis2” from the input shape and appending to the result a new axis with the size of the diagonals in question.

For example, when the input shape is ‘(2, 3, 4, 5)’, “axis1” and “axis2” are 0 and 2 respectively and “k” is 0, the resulting shape would be ‘(3, 5, 2)’.

Examples:

x = [[1, 2, 3], [4, 5, 6]]

diag(x) = [1, 5]

diag(x, k=1) = [2, 6]

diag(x, k=-1) = [4]

x = [1, 2, 3]

diag(x) = [[1, 0, 0], [0, 2, 0], [0, 0, 3]]

diag(x, k=1) = [[0, 1, 0], [0, 0, 2], [0, 0, 0]]

diag(x, k=-1) = [[0, 0, 0], [1, 0, 0], [0, 2, 0]]

x = [[[1, 2], [3, 4]], [[5, 6], [7, 8]]]

diag(x) = [[1, 7], [2, 8]]

diag(x, k=1) = [[3], [4]]

diag(x, axis1=-2, axis2=-1) = [[1, 4], [5, 8]]

Defined in src/operator/tensor/diag_op.cc:L87

Value

out The result mx.ndarray

mx.nd.dot

Dot product of two arrays.

Description

“dot”‘s behavior depends on the input array dimensions:
Arguments

- **lhs**: NDArray-or-Symbol The first input
- **rhs**: NDArray-or-Symbol The second input
- **transpose.a**: boolean, optional, default=0 If true then transpose the first input before dot.
- **transpose.b**: boolean, optional, default=0 If true then transpose the second input before dot.
- **forward.stype**: None, 'csr', 'default', 'row_sparse', optional, default='None' The desired storage type of the forward output given by user, if the combination of input storage types and this hint does not match any implemented ones, the dot operator will perform fallback operation and still produce an output of the desired storage type.

Details

- 1-D arrays: inner product of vectors - 2-D arrays: matrix multiplication - N-D arrays: a sum product over the last axis of the first input and the first axis of the second input

For example, given 3-D “x” with shape ‘(n,m,k)’ and “y” with shape ‘(k,r,s)’, the result array will have shape ‘(n,m,r,s)’. It is computed by:

\[
dot(x,y)[i,j,a,b] = \sum(x[i,j,:]*y[:,a,b])
\]

Example:

\[
x = \text{reshape}([0,1,2,3,4,5,6,7], \text{shape}=(2,2,2)) \quad y = \text{reshape}([7,6,5,4,3,2,1,0], \text{shape}=(2,2,2))
\]

\[
dot(x,y)[0,0,1,1] = 0 \quad \sum(x[0,0,:]*y[:,1,1]) = 0
\]

The storage type of “dot” output depends on storage types of inputs, transpose option and forward_stype option for output storage type. Implemented sparse operations include:

- `dot(default, default, transpose_a=True/False, transpose_b=True/False) = default`
- `dot(csr, default, transpose_a=True) = default`
- `dot(csr, default, transpose_a=True) = row_sparse`
- `dot(csr, default) = default`
- `dot(csr, row_sparse) = default`
- `dot(default, csr, transpose_b=True, forward_stype='default') = default`
- `dot(default, csr, transpose_b=True, forward_stype='default') = default`

If the combination of input storage types and forward_stype does not match any of the above patterns, “dot” will fallback and generate output with default storage.

.. Note::

If the storage type of the lhs is "csr", the storage type of gradient w.r.t rhs will be "row_sparse". Only a subset of optimizers support sparse gradients, including SGD, AdaGrad and Adam. Note that by default lazy updates is turned on, which may perform differently from standard updates. For more details, please check the Optimization API at: https://mxnet.incubator.apache.org/api/python/optimization/optimization.html

Defined in src/operator/tensor/dot.cc:L77

Value

- **out**: The result mx.ndarray
mx.nd.Dropout

Applies dropout operation to input array.

Description

- During training, each element of the input is set to zero with probability p. The whole array is rescaled by \( \frac{1}{1-p} \) to keep the expected sum of the input unchanged.

Arguments

data

NDArray-or-Symbol Input array to which dropout will be applied.

p

float, optional, default=0.5 Fraction of the input that gets dropped out during training time.

mode

‘always’, ‘training’, optional, default=’training’ Whether to only turn on dropout during training or to also turn on for inference.

axes

Shape(tuple), optional, default=[] Axes for variational dropout kernel.

cudnn_off

boolean or None, optional, default=0 Whether to turn off cudnn in dropout operator. This option is ignored if axes is specified.

Details

- During testing, this operator does not change the input if mode is ’training’. If mode is ’always’, the same computation as during training will be applied.

Example::

random.seed(998) input_array = array([[3., 0.5, -0.5, 2., 7.], [2., -0.4, 7., 3., 0.2]]) a = symbol.Variable('a') dropout = symbol.Dropout(a, p = 0.2) executor = dropout.simple_bind(a = input_array.shape)

## If training executor.forward(is_train = True, a = input_array) executor.outputs [[ 3.75 0.625 -0.2.5 8.75 ] [ 2.5 -0.5 8.75 3.75 0. ]] 

## If testing executor.forward(is_train = False, a = input_array) executor.outputs [[ 3. 0.5 -0.5 2.7. ] [ 2. -0.4 7. 3. 0.2 ]] 

Defined in src/operator/nn/dropout.cc:L96

Value

out The result mx.ndarray
**mx.nd.ElementWiseSum**  
Adds all input arguments element-wise.

**Description**

.. math:: \text{add}_n(a_1, a_2, ..., a_n) = a_1 + a_2 + ... + a_n

**Arguments**

- **args**: NDArray-or-Symbol[]): Positional input arguments

**Details**

“add_n” is potentially more efficient than calling “add” by ‘n’ times.

The storage type of “add_n” output depends on storage types of inputs

- \text{add}_n(\text{row_sparse, row_sparse, ...}) = \text{row_sparse}
- \text{add}_n(\text{default}, \text{csr}, \text{default}) = \text{default}
- \text{add}_n(\text{any input combinations longer than 4 (>4) with at least one default type}) = \text{default}
- otherwise, “add_n” falls all inputs back to default storage and generates default storage

Defined in src/operator/tensor/elemwise_sum.cc:L156

**Value**

- **out**: The result mx.ndarray

**mx.nd.elemwise.add**  
Adds arguments element-wise.

**Description**

The storage type of “elemwise_add” output depends on storage types of inputs

**Arguments**

- **lhs**: NDArray-or-Symbol first input
- **rhs**: NDArray-or-Symbol second input

**Details**

- \text{elemwise_add(\text{row_sparse, row_sparse}) = \text{row_sparse}}
- \text{elemwise_add(\text{csr, csr}) = \text{csr}}
- \text{elemwise_add(\text{default, csr}) = \text{default}}
- \text{elemwise_add(\text{csr, default}) = \text{default}}
- \text{elemwise_add(\text{default, rsp}) = \text{default}}
- \text{elemwise_add(\text{rsp, default}) = \text{default}}
- otherwise, “elemwise_add” generates output with default storage

**Value**

- **out**: The result mx.ndarray
**mx.nd.elemwise.div**  *Divides arguments element-wise.*

**Description**

The storage type of “elemwise_div” output is always dense

**Arguments**

- **lhs**  
  NDArray-or-Symbol first input
- **rhs**  
  NDArray-or-Symbol second input

**Value**

- **out**  
  The result mx.ndarray

---

**mx.nd.elemwise.mul**  *Multiplies arguments element-wise.*

**Description**

The storage type of “elemwise_mul” output depends on storage types of inputs

**Arguments**

- **lhs**  
  NDArray-or-Symbol first input
- **rhs**  
  NDArray-or-Symbol second input

**Details**

- elemwise_mul(default, default) = default - elemwise_mul(row_sparse, row_sparse) = row_sparse - elemwise_mul(default, row_sparse) = row_sparse - elemwise_mul(row_sparse, default) = row_sparse - elemwise_mul(csr, csr) = csr - otherwise, “elemwise_mul” generates output with default storage

**Value**

- **out**  
  The result mx.ndarray
mx.nd.elemwise_sub

Subtracts arguments element-wise.

Description
The storage type of “elemwise_sub” output depends on storage types of inputs.

Arguments
- lhs: NDArray-or-Symbol first input
- rhs: NDArray-or-Symbol second input

Details
- elemwise_sub(row_sparse, row_sparse) = row_sparse - elemwise_sub(csr, csr) = csr - elemwise_sub(default, csr) = default - elemwise_sub(csr, default) = default - elemwise_sub(default, rsp) = default - elemwise_sub(rsp, default) = default - otherwise, “elemwise_sub” generates output with default storage

Value
- out: The result mx.ndarray

mx.nd.Embedding
Maps integer indices to vector representations (embeddings).

Description
This operator maps words to real-valued vectors in a high-dimensional space, called word embeddings. These embeddings can capture semantic and syntactic properties of the words. For example, it has been noted that in the learned embedding spaces, similar words tend to be close to each other and dissimilar words far apart.

Arguments
- data: NDArray-or-Symbol The input array to the embedding operator.
- weight: NDArray-or-Symbol The embedding weight matrix.
- input.dim: int, required Vocabulary size of the input indices.
- output.dim: int, required Dimension of the embedding vectors.
- sparse.grad: boolean, optional, default=0 Compute row sparse gradient in the backward calculation. If set to True, the grad’s storage type is row_sparse.
Details

For an input array of shape (d1, ..., dK), the shape of an output array is (d1, ..., dK, output_dim). All the input values should be integers in the range [0, input_dim).

If the input_dim is ip0 and output_dim is op0, then shape of the embedding weight matrix must be (ip0, op0).

When "sparse_grad" is False, if any index mentioned is too large, it is replaced by the index that addresses the last vector in an embedding matrix. When "sparse_grad" is True, an error will be raised if invalid indices are found.

Examples::

input_dim = 4 output_dim = 5
// Each row in weight matrix y represents a word. So, y = (w0,w1,w2,w3) y = [[ 0., 1., 2., 3., 4.], [ 5., 6., 7., 8., 9.], [ 10., 11., 12., 13., 14.], [ 15., 16., 17., 18., 19.]]
// Input array x represents n-grams(2-gram). So, x = [(w1,w3), (w0,w2)] x = [[ 1., 3.], [ 0., 2.]]
// Mapped input x to its vector representation y. Embedding(x, y, 4, 5) = [[[ 5., 6., 7., 8., 9.], [ 15., 16., 17., 18., 19.]], [[ 0., 1., 2., 3., 4.], [ 10., 11., 12., 13., 14.]]]

The storage type of weight can be either row_sparse or default.

.. Note::

If "sparse_grad" is set to True, the storage type of gradient w.r.t weights will be "row_sparse". Only a subset of optimizers support sparse gradients, including SGD, AdaGrad and Adam. Note that by default lazy updates is turned on, which may perform differently from standard updates. For more details, please check the Optimization API at: https://mxnet.incubator.apache.org/api/python/optimization/optimization.html

Defined in src/operator/tensor/indexing_op.cc:L598

Value

out The result mx.ndarray

mx.nd.erf

Returns element-wise gauss error function of the input.

Description

Example::

Arguments

data NDArray-or-Symbol The input array.

Details

erf([0, -1., 10.]) = [0., -0.8427, 1.]

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L886
mx.nd.erfinv

Returns element-wise inverse gauss error function of the input.

Value
out The result mx.ndarray

mx.nd.exp
Returns element-wise exponential value of the input.

Description
.. math:: \exp(x) = e^x \approx 2.718^x

Arguments
data NDArray-or-Symbol The input array.

Details
Example::
\exp([0, 1, 2]) = [1., 2.71828175, 7.38905621]
The storage type of “exp” output is always dense
Defined in src/operator/tensor/elemwise_unary_op_logexp.cc:L64

Value
out The result mx.ndarray
**mx.nd.expand_dims**

Inserts a new axis of size 1 into the array shape. For example, given “x” with shape “(2,3,4)”, then “expand_dims(x, axis=1)” will return a new array with shape “(2,1,3,4)”.

**Description**

Defined in src/operator/tensor/matrix_op.cc:L395

**Arguments**

- **data**  
  NDArray-or-Symbol  
  Source input

- **axis**  
  int, required  
  Position where new axis is to be inserted. Suppose that the input ‘NDArray’’s dimension is ‘ndim’, the range of the inserted axis is ‘[-ndim, ndim]’

**Value**

- **out**  
  The result mx.ndarray

---

**mx.nd.expm1**

Returns “exp(x) - 1” computed element-wise on the input.

**Description**

This function provides greater precision than “exp(x) - 1” for small values of “x”.

**Arguments**

- **data**  
  NDArray-or-Symbol  
  The input array.

**Details**

The storage type of “expm1” output depends upon the input storage type:

- expm1(default) = default - expm1(row_sparse) = row_sparse - expm1(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_logexp.cc:L244

**Value**

- **out**  
  The result mx.ndarray
mx.nd.fill.element.0index

Fill one element of each line (row for python, column for R/Julia) in lhs according to index indicated by rhs and values indicated by mhs. This function assume rhs uses 0-based index.

Description
Fill one element of each line (row for python, column for R/Julia) in lhs according to index indicated by rhs and values indicated by mhs. This function assume rhs uses 0-based index.

Arguments
- **lhs**: NDArray Left operand to the function.
- **mhs**: NDArray Middle operand to the function.
- **rhs**: NDArray Right operand to the function.

Value
- **out**: The result mx.ndarray

mx.nd.fix

Returns element-wise rounded value to the nearest integer towards zero of the input.

Description
Example::

Arguments
- **data**: NDArray-or-Symbol The input array.

Details
- fix([-2.1, -1.9, 1.9, 2.1]) = [-2., -1., 1., 2.]
  The storage type of “fix” output depends upon the input storage type:
  - fix(default) = default - fix(row_sparse) = row_sparse - fix(csr) = csr
  Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L874

Value
- **out**: The result mx.ndarray
Flattens the input array into a 2-D array by collapsing the higher dimensions. .. note:: ‘Flatten’ is deprecated. Use ‘flatten’ instead. For an input array with shape “(d1, d2, ..., dk)”, ‘flatten’ operation reshapes the input array into an output array of shape “(d1, d2*...*dk)”. Note that the behavior of this function is different from numpy.ndarray.flatten, which behaves similar to mxnet.ndarray.reshape((-1,)). Example::

```py
x = [[[1,2,3], [4,5,6], [7,8,9]], [[1,2,3], [4,5,6], [7,8,9]]]
flatten(x) = [[[1, 2, 3, 4, 5, 6, 7, 8, 9]], [[1, 2, 3, 4, 5, 6, 7, 8, 9]]]
```

## Description
Defined in src/operator/tensor/matrix_op.cc:L250

## Arguments
- **data**: NDArray-or-Symbol Input array.

## Value
- **out**: The result mx.ndarray

---

Flattens the input array into a 2-D array by collapsing the higher dimensions. .. note:: ‘Flatten’ is deprecated. Use ‘flatten’ instead. For an input array with shape “(d1, d2, ..., dk)”, ‘flatten’ operation reshapes the input array into an output array of shape “(d1, d2*...*dk)”. Note that the behavior of this function is different from numpy.ndarray.flatten, which behaves similar to mxnet.ndarray.reshape((-1,)). Example::

```py
x = [[[1,2,3], [4,5,6], [7,8,9]], [[1,2,3], [4,5,6], [7,8,9]]]
flatten(x) = [[[1, 2, 3, 4, 5, 6, 7, 8, 9]], [[1, 2, 3, 4, 5, 6, 7, 8, 9]]]
```

## Description
Defined in src/operator/tensor/matrix_op.cc:L250

## Arguments
- **data**: NDArray-or-Symbol Input array.

## Value
- **out**: The result mx.ndarray
### mx.nd.flip

Reverses the order of elements along given axis while preserving array shape. Note: reverse and flip are equivalent. We use reverse in the following examples. Examples:

\[
x = [[0., 1., 2., 3., 4.], [5., 6., 7., 8., 9.]]
reverse(x, axis=0) = [[5., 6., 7., 8., 9.], [0., 1., 2., 3., 4.]]
reverse(x, axis=1) = [[4., 3., 2., 1., 0.], [9., 8., 7., 6., 5.]]
\]

**Description**

Defined in `src/operator/tensor/matrix_op.cc:L832`

**Arguments**

- **data**: NDArray-or-Symbol
  Input data array

- **axis**: Shape(tuple), required
  The axis which to reverse elements.

**Value**

- **out**: The result `mx.ndarray`

### mx.nd.floor

Returns element-wise floor of the input.

**Description**

The floor of the scalar x is the largest integer i, such that i <= x.

**Arguments**

- **data**: NDArray-or-Symbol
  The input array.

**Details**

Example:

\[
\text{floor}([-2.1, -1.9, 1.5, 1.9, 2.1]) = [-3., -2., 1., 1., 2.]
\]

The storage type of “floor“ output depends upon the input storage type:

- floor(default) = default
- floor(row_sparse) = row_sparse
- floor(csr) = csr

Defined in `src/operator/tensor/elemwise_unary_op_basic.cc:L836`

**Value**

- **out**: The result `mx.ndarray`

## Description

.. math::

## Arguments

- **weight**: NDArray-or-Symbol Weight
- **grad**: NDArray-or-Symbol Gradient
- **d**: NDArray-or-Symbol Internal state “d_t”
- **v**: NDArray-or-Symbol Internal state “v_t”
- **z**: NDArray-or-Symbol Internal state “z_t”
- **lr**: float, required Learning rate.
- **beta1**: float, optional, default=0.600000024 Generally close to 0.5.
- **beta2**: float, optional, default=0.999000013 Generally close to 1.
- **epsilon**: double, optional, default=9.9999999392252903e-09 Epsilon to prevent div 0.
- **t**: int, required Number of update.
- **wd**: float, optional, default=0 Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
- **rescale.grad**: float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
- **clip.grad**: float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient] If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).

## Details

\[
g_t = \nabla \text{J}(W_{t-1}) \quad v_{t} = \beta_2 v_{t-1} + (1 - \beta_2) g_t^2 \quad d_{t} = \frac{1}{1 - \beta_1^t} \eta_t (\sqrt{v_t} + \epsilon) \quad \sigma_t = d_t - \beta_1 d_{t-1} \quad z_t = \beta_1 z_{t-1} + (1 - \beta_1^t) g_t - \sigma_t W_{t-1} \quad W_t = -\frac{z_t d_t}{z_t d_t}
\]

Defined in src/operator/optimizer_op.cc:L640

## Value

- **out**: The result mx.ndarray

**Description**

It updates the weights using::

**Arguments**

- **weight**: NDArray-or-Symbol Weight
- **grad**: NDArray-or-Symbol Gradient
- **z**: NDArray-or-Symbol z
- **n**: NDArray-or-Symbol Square of grad
- **lr**: float, required Learning rate
- **lamda1**: float, optional, default=0.00999999978 The L1 regularization coefficient.
- **beta**: float, optional, default=1 Per-Coordinate Learning Rate beta.
- **wd**: float, optional, default=0 Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
- **rescale.grad**: float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
- **clip.gradient**: float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient] If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).

**Details**

rescaled_grad = clip(grad * rescale_grad, clip_gradient) z += rescaled_grad - (sqrt(n + rescaled_grad**2) - sqrt(n)) * weight / learning_rate n += rescaled_grad**2 w = (sign(z) * lamda1 - z) / ((beta + sqrt(n)) / learning_rate + wd) * (abs(z) > lamda1)

If w, z and n are all of “row_sparse” storage type, only the row slices whose indices appear in grad.indices are updated (for w, z and n):

Defined in src/operator/optimizer_op.cc:L876

**Value**

out The result mx.ndarray
mx.nd.FullyConnected  

Applies a linear transformation: \( Y = XW^T + b \).

**Description**

If “flatten” is set to be true, then the shapes are:

**Arguments**

- **data**: NDArray-or-Symbol Input data.
- **weight**: NDArray-or-Symbol Weight matrix.
- **bias**: NDArray-or-Symbol Bias parameter.
- **num.hidden**: int, required Number of hidden nodes of the output.
- **no.bias**: boolean, optional, default=0 Whether to disable bias parameter.
- **flatten**: boolean, optional, default=1 Whether to collapse all but the first axis of the input data tensor.

**Details**

- **data**: ‘(batch_size, x1, x2, ..., xn)’
- **weight**: ‘(num_hidden, x1 * x2 * ... * xn)’
- **bias**: ‘(num_hidden,)’
- **out**: ‘(batch_size, num_hidden)’

If “flatten” is set to be false, then the shapes are:

- **data**: ‘(x1, x2, ..., xn, input_dim)’
- **weight**: ‘(num_hidden, input_dim)’
- **bias**: ‘(num_hidden,)’
- **out**: ‘(x1, x2, ..., xn, num_hidden)’

The learnable parameters include both “weight” and “bias”.

If “no.bias” is set to be true, then the “bias” term is ignored.

.. Note::

The sparse support for FullyConnected is limited to forward evaluation with ‘row_sparse’ weight and bias, where the length of ‘weight.indices’ and ‘bias.indices’ must be equal to ‘num_hidden’. This could be useful for model inference with ‘row_sparse’ weights trained with importance sampling or noise contrastive estimation.

To compute linear transformation with ’csr’ sparse data, sparse.dot is recommended instead of sparse.FullyConnected.

Defined in src/operator/nn/fully_connected.cc:L287

**Value**

- **out**: The result mx.ndarray
mx.nd.gamma

Returns the gamma function (extension of the factorial function to the reals), computed element-wise on the input array.

Description
The storage type of “gamma“ output is always dense

Arguments
- data NDArray-or-Symbol The input array.

Value
- out The result mx.nd.array

mx.nd.gammaln

Returns element-wise log of the absolute value of the gamma function of the input.

Description
The storage type of “gammaln“ output is always dense

Arguments
- data NDArray-or-Symbol The input array.

Value
- out The result mx.nd.array
mx.nd.gather.nd  
Gather elements or slices from ‘data’ and store to a tensor whose shape is defined by ‘indices’.

**Description**

Given ‘data’ with shape ‘(X_0, X_1, ..., X_N-1)’ and indices with shape ‘(M, Y_0, ..., Y_K-1)’, the output will have shape ‘(Y_0, ..., Y_K-1, X_M, ..., X_N-1)’, where ‘M <= N’. If ‘M == N’, output shape will simply be ‘(Y_0, ..., Y_K-1)’.

**Arguments**

- **data**  
  NDArray-or-Symbol data

- **indices**  
  NDArray-or-Symbol indices

**Details**

The elements in output is defined as follows::

\[
\text{output}[y_0, ..., y_K-1, x_M, ..., x_N-1] = data[\text{indices}[0, y_0, ..., y_K-1], ..., \text{indices}[M-1, y_0, ..., y_K-1], x_M, ..., x_N-1]
\]

**Examples::**

- data = [[0, 1], [2, 3]] indices = [[1, 1, 0], [0, 1, 0]]  
gather_nd(data, indices) = [2, 3, 0]

- data = [[[1, 2], [3, 4]], [[5, 6], [7, 8]]] indices = [[0, 1], [1, 0]]  
gather_nd(data, indices) = [[3, 4], 5, 6]]

**Value**

- out The result mx.nd.array

mx.nd.GridGenerator  
Generates 2D sampling grid for bilinear sampling.

**Description**

Generates 2D sampling grid for bilinear sampling.

**Arguments**

- **data**  
  NDArray-or-Symbol Input data to the function.

- **transform.type**  
  "affine", "warp", required The type of transformation. For "affine", input data should be an affine matrix of size (batch, 6). For "warp", input data should be an optical flow of size (batch, 2, h, w).

- **target.shape**  
  Shape(tuple), optional, default=[0,0] Specifies the output shape (H, W). This is required if transformation type is "affine". If transformation type is "warp", this parameter is ignored.
**mx.nd.GroupNorm**

**Value**

out The result mx.ndarray

---

**mx.nd.GroupNorm**  
*Group normalization.*

**Description**

The input channels are separated into “num_groups” groups, each containing “num_channels / num_groups“ channels. The mean and standard-deviation are calculated separately over the each group.

**Arguments**

- **data**: NDArray-or-Symbol  
  Input data
- **gamma**: NDArray-or-Symbol  
  gamma array
- **beta**: NDArray-or-Symbol  
  beta array
- **num.groups**: int, optional, default='1'  
  Total number of groups.
- **eps**: float, optional, default=9.99999975e-06  
  An ‘epsilon’ parameter to prevent division by 0.
- **output.mean.var**: boolean, optional, default=0  
  Output the mean and std calculated along the given axis.

**Details**

.. math::

\[
data = data.reshape((N, num\_groups, C // num\_groups, ...))  
out = \frac{data - mean(data, axis)\sqrt{var(data, axis)}}{\epsilon} * gamma + beta
\]

Both “gamma” and “beta” are learnable parameters.

Defined in src/operator/nn/group_norm.cc:L77

**Value**

out The result mx.ndarray
mx.nd.hard.sigmoid  Computes hard sigmoid of $x$ element-wise.

Description

.. math:: y = \max(0, \min(1, \alpha \cdot x + \beta))

Arguments

data  NDArray-or-Symbol The input array.
alpha  float, optional, default=0.2 Slope of hard sigmoid
beta   float, optional, default=0.5 Bias of hard sigmoid.

Details

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L161

Value

out The result mx.ndarray

mx.nd.identity  Returns a copy of the input.

Description

From:src/operator/tensor/elemwise_unary_op_basic.cc:244

Arguments

data  NDArray-or-Symbol The input array.

Value

out The result mx.ndarray
**mx.nd.IdentityAttachKLSparseReg**

Apply a sparse regularization to the output a sigmoid activation function.

**Description**

Apply a sparse regularization to the output a sigmoid activation function.

**Arguments**

- **data** NDArray-or-Symbol Input data.
- **sparseness.target** float, optional, default=0.100000001 The sparseness target
- **penalty** float, optional, default=0.00100000005 The tradeoff parameter for the sparseness penalty
- **momentum** float, optional, default=0.899999976 The momentum for running average

**Value**

- **out** The result mx.ndarray

---

**mx.nd.im2col**

Extract sliding blocks from input array.

**Description**

This operator is used in vanilla convolution implementation to transform the sliding blocks on image to column matrix, then the convolution operation can be computed by matrix multiplication between column and convolution weight. Due to the close relation between im2col and convolution, the concept of **kernel**, **stride**, **dilate** and **pad** in this operator are inherited from convolution operation.

**Arguments**

- **data** NDArray-or-Symbol Input array to extract sliding blocks.
- **kernel** Shape(tuple), required Sliding kernel size: (w,), (h, w) or (d, h, w).
- **stride** Shape(tuple), optional, default=[] The stride between adjacent sliding blocks in spatial dimension: (w,), (h, w) or (d, h, w). Defaults to 1 for each dimension.
- **dilate** Shape(tuple), optional, default=[] The spacing between adjacent kernel points: (w,), (h, w) or (d, h, w). Defaults to 1 for each dimension.
- **pad** Shape(tuple), optional, default=[] The zero-value padding size on both sides of spatial dimension: (w,), (h, w) or (d, h, w). Defaults to no padding.
Details

Given the input data of shape \( \text{shape}(N, C, \ast) \), where \( N \) is the batch size, \( C \) is the channel size, and \( \ast \) is the arbitrary spatial dimension, the output column array is always with shape \( \text{shape}(N, C \times \prod(\text{kernel}), W) \), where \( C \times \prod(\text{kernel}) \) is the block size, and \( W \) is the block number which is the spatial size of the convolution output with same input parameters. Only 1-D, 2-D and 3-D of spatial dimension is supported in this operator.

Defined in src/operator/nn/im2col.cc:L100

Value

out The result mx.ndarray

---

mx.nd.InstanceNorm
Applies instance normalization to the n-dimensional input array.

Description

This operator takes an n-dimensional input array where \( n>2 \) and normalizes the input using the following formula:

\[
\text{out} = \frac{x - \text{mean}[\text{data}]}{\sqrt{\text{Var}[\text{data}]} + \epsilon} \times \gamma + \beta
\]

This layer is similar to batch normalization layer (‘BatchNorm’) with two differences: first, the normalization is carried out per example (instance), not over a batch. Second, the same normalization is applied both at test and train time. This operation is also known as ‘contrast normalization’.

If the input data is of shape \([\text{batch, channel, spatial}_1, \text{spacial}_2, \ldots]\), ‘gamma’ and ‘beta’ parameters must be vectors of shape \([\text{channel}]\).

This implementation is based on this paper [1]

Examples:
// Input of shape (2,1,2) x = [[[ 1.1, 2.2]], [[ 3.3, 4.4]]]
// gamma parameter of length 1 gamma = [1.5]
// beta parameter of length 1 beta = [0.5]
// Instance normalization is calculated with the above formula InstanceNorm(x,gamma,beta) = [[[-0.997527 , 1.99752665]], [[-0.99752653, 1.99752724]]]
Defined in src/operator/instance_norm.cc:L95

Value

out The result mx.ndarray

mx.nd.khatri_rao

Computes the Khatri-Rao product of the input matrices.

Description

Given a collection of \('n\) input matrices,

Arguments

args NDArray-or-Symbol[] Positional input matrices

Details

.. math:: A_1 \in \mathbb{R}^{M_1 \times N}, \ldots, A_n \in \mathbb{R}^{M_n \times N},
the (column-wise) Khatri-Rao product is defined as the matrix,

.. math:: X = A_1 \otimes \cdots \otimes A_n \in \mathbb{R}^{(M_1 \cdots M_n) \times N},

where the \('k\) th column is equal to the column-wise outer product :math:`A_1 \_k \otimes \cdots \otimes A_n \_k` where :math:`A_\_i \_k` is the \(k\)th column of the \(i\)th matrix.

Example::

```python
>> A = mx.nd.array([[1, -1], [2, -3]])
>> B = mx.nd.array([[1, 4], [2, 5], [3, 6]])
>> C = mx.nd.khatri_rao(A, B)
>> print(C.asnumpy())
[[ 1. -4.]
 [ 2. -12.]
 [ 4. -15.]
 [ 6. -18.]]
```
Defined in src/operator/contrib/krprod.cc:L108

Value

out The result mx.ndarray
**mx.nd.L2Normalization**  
Normalize the input array using the L2 norm.

**Description**

For 1-D NDArray, it computes::

**Arguments**

- **data**  
  NDArray-or-Symbol Input array to normalize.

- **eps**  
  float, optional, default=1.00000001e-10 A small constant for numerical stability.

- **mode**  
  'channel', 'instance', 'spatial',optional, default='instance' Specify the dimension along which to compute L2 norm.

**Details**

\[
out = \frac{data}{\sqrt{\text{sum}(data^2) + \text{eps}}}
\]

For N-D NDArray, if the input array has shape (N, N, ..., N),
with "mode" = "instance", it normalizes each instance in the multidimensional array by its L2 norm::

\[
\text{for } i \text{ in } 0...N \text{ out}[i,:,:,:,:] = \frac{\text{data}[i,:,:,:,:]}{\sqrt{\text{sum}(\text{data}[i,:,:,:,:]^2) + \text{eps}}}
\]

with "mode" = "channel", it normalizes each channel in the array by its L2 norm::

\[
\text{for } i \text{ in } 0...N \text{ out}[;i,:,:,:,:] = \frac{\text{data}[;i,:,:,:,:]}{\sqrt{\text{sum}(\text{data}[;i,:,:,:,:]^2) + \text{eps}}}
\]

with "mode" = "spatial", it normalizes the cross channel norm for each position in the array by its L2 norm::

\[
\text{for dim in } 2...N \text{ for } i \text{ in } 0...N \text{ out}[.....,i,...] = \frac{\text{take(out, indices=i, axis=dim)}}{\sqrt{\text{sum}(\text{take(out, indices=i, axis=dim})^2 + \text{eps}) -\text{dim}-}}
\]

**Example**::

```python
x = [[[1,2], [3,4]], [[2,2], [5,6]]]
L2Normalization(x, mode='instance') =[[[ 0.18257418 0.36514837] [ 0.54772252 0.73029673]] [[ 0.24077171 0.24077171] [ 0.60192931 0.72231513]]]
L2Normalization(x, mode='channel') =[[[ 0.31622776 0.44721359] [ 0.94868326 0.89442718]] [[ 0.37139067 0.31622776] [ 0.92847669 0.94868326]]]
L2Normalization(x, mode='spatial') =[[[ 0.44721359 0.89442718] [ 0.60000002 0.80000001]] [[ 0.70710677 0.70710677] [ 0.6401844 0.76822126]]]
```

Defined in src/operator/l2_normalization.cc:L196

**Value**

- `out` The result mx.ndarray
Phase I of lamb update it performs the following operations and returns g:

Defined in src/operator/optimizer_op.cc:L953

Value

out The result mx.nd.array
mx.nd.lamb.update.phase2

Phase II of lamb update it performs the following operations and updates grad.

Description

Arguments

- **weight**: NDArray-or-Symbol Weight
- **g**: NDArray-or-Symbol Output of lamb_update_phase 1
- **r1**: NDArray-or-Symbol r1
- **r2**: NDArray-or-Symbol r2
- **lr**: float, required Learning rate
- **lower.bound**: float, optional, default=-1 Lower limit of norm of weight. If lower_bound <= 0, Lower limit is not set
- **upper.bound**: float, optional, default=-1 Upper limit of norm of weight. If upper_bound <= 0, Upper limit is not set

Details

.. math:: \begin{align*}
  &\text{if (lower_bound} \geq 0) \text{ then } r1 = \max(r1, \text{lower_bound}) \text{ if (upper_bound} \geq 0) \text{ then } r1 = \max(r1, \text{upper_bound}) \\
  &\text{if (}r1 \text{ == 0 or } r2 \text{ == 0) then } lr = lr \text{ else } lr = lr \times (r1/r2) \text{ weight = weight - lr * g }\end{align*}

Defined in src/operator/optimizer_op.cc:L992

Value

- **out**: The result mx.ndarray

mx.nd.LayerNorm

Layer normalization.

Description

Normalizes the channels of the input tensor by mean and variance, and applies a scale “gamma” as well as offset “beta”.
mx.nd.LeakyReLU

**Arguments**

- **data**
  NDArray-or-Symbol Input data to layer normalization
- **gamma**
  NDArray-or-Symbol gamma array
- **beta**
  NDArray-or-Symbol beta array
- **axis**
  int, optional, default='-1' The axis to perform layer normalization. Usually, this should be the axis of the channel dimension. Negative values mean indexing from right to left.
- **eps**
  float, optional, default=9.99999975e-06 An ‘epsilon’ parameter to prevent division by 0.
- **output.mean.var**
  boolean, optional, default=0 Output the mean and std calculated along the given axis.

**Details**

Assume the input has more than one dimension and we normalize along axis 1. We first compute the mean and variance along this axis and then compute the normalized output, which has the same shape as input, as following:

\[
\text{out} = \frac{\text{data} - \text{mean}(\text{data}, \text{axis})}{\sqrt{\text{var}(\text{data}, \text{axis})}} + \epsilon * \text{gamma} + \text{beta}
\]

Both “gamma” and “beta” are learnable parameters.

Unlike BatchNorm and InstanceNorm, the *mean* and *var* are computed along the channel dimension.

Assume the input has size *k* on axis 1, then both “gamma” and “beta” have shape *(k,)*. If “output_mean_var” is set to be true, then outputs both “data_mean” and “data_std”. Note that no gradient will be passed through these two outputs.

The parameter “axis” specifies which axis of the input shape denotes the ‘channel’ (separately normalized groups). The default is -1, which sets the channel axis to be the last item in the input shape.

Defined in src/operator/nn/layer_norm.cc:L159

**Value**

- **out** The result mx.ndarray

---

**mx.nd.LeakyReLU**

Applies Leaky rectified linear unit activation element-wise to the input.

**Description**

Leaky ReLUs attempt to fix the "dying ReLU" problem by allowing a small ‘slope’ when the input is negative and has a slope of one when input is positive.
Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>NDArray-or-Symbol Input data to activation function.</td>
</tr>
<tr>
<td>gamma</td>
<td>NDArray-or-Symbol Input data to activation function.</td>
</tr>
<tr>
<td>act.type</td>
<td>'elu', 'gelu', 'leaky', 'prelu', 'relu', 'selu', optional, default='leaky' Activation function to be applied.</td>
</tr>
<tr>
<td>slope</td>
<td>float, optional, default=0.25 Init slope for the activation. (For leaky and elu only)</td>
</tr>

</tr>
<tr>
<td>upper.bound</td>
<td>float, optional, default=0.333999991 Upper bound of random slope. (For relu only)</td>
</tr>
</tbody>
</table>

Details

The following modified ReLU Activation functions are supported:

- *elu*: Exponential Linear Unit. \( y = x > 0 \ ? \ x : \text{slope} \cdot (\exp(x)-1) \)
- *selu*: Scaled Exponential Linear Unit. \( y = \lambda \cdot (x > 0 \ ? \ x : \alpha \cdot (\exp(x) - 1)) \) where \( \lambda = 1.0507009873554804934193349852946 \) and \( \alpha = 1.6732632423543772848170429916717 \).
- *leaky*: Leaky ReLU. \( y = x > 0 \ ? \ x : \text{slope} \cdot x \)
- *prelu*: Parametric ReLU. This is same as *leaky* except that 'slope' is learnt during training.
- *rrelu*: Randomized ReLU. same as *leaky* but the 'slope' is uniformly and randomly chosen from \([\text{lower bound, upper bound})\) for training, while fixed to be \( \frac{\text{lower bound}+\text{upper bound}}{2} \) for inference.

Defined in src/operator/leaky_relu.cc:L163

Value

out The result mx.ndarray

mx.nd.linalg.det

Compute the determinant of a matrix. Input is a tensor *A* of dimension *n >= 2*.

Description

If *n=2*, *A* is a square matrix. We compute:

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>NDArray-or-Symbol Tensor of square matrix</td>
</tr>
</tbody>
</table>
mx.nd.linalg.extractdiag

Extracts the diagonal entries of a square matrix. Input is a tensor *A* of dimension *n* >= 2.

**Description**

If *n*=2*, then *A* represents a single square matrix which diagonal elements get extracted as a 1-dimensional tensor.

**Arguments**

- **A**
  - NDArray-or-Symbol Tensor of square matrices
- **offset**
  - int, optional, default=’0’ Offset of the diagonal versus the main diagonal. 0 corresponds to the main diagonal, a negative/positive value to diagonals below/above the main diagonal.

**Details**

If *n>2*, then *A* represents a batch of square matrices on the trailing two dimensions. The extracted diagonals are returned as an *n-1*-dimensional tensor.

.. note:: The operator supports float32 and float64 data types only.

**Examples**:

Single matrix diagonal extraction

```
A = [[1.0, 2.0], [3.0, 4.0]]
e = extractdiag(A) = [1.0, 4.0]
e = extractdiag(A, 1) = [2.0]
```

Batch matrix diagonal extraction

```
A = [[[1.0, 2.0], [3.0, 4.0]], [[5.0, 6.0], [7.0, 8.0]]]
e = extractdiag(A) = [1.0, 4.0, 6.0, 8.0]
e = extractdiag(A, 1) = [2.0, 6.0, 8.0]
```
mx.nd.linalg.extractttrian

Extracts a triangular sub-matrix from a square matrix. Input is a tensor *A* of dimension *n >= 2*.

**Description**

If *n=2*, then *A* represents a single square matrix from which a triangular sub-matrix is extracted as a 1-dimensional tensor.

**Arguments**

- **A**: NDArray-or-Symbol Tensor of square matrices
- **offset**: int, optional, default='0' Offset of the diagonal versus the main diagonal. 0 corresponds to the main diagonal, a negative/positive value to diagonals below/above the main diagonal.
- **lower**: boolean, optional, default=1 Refer to the lower triangular matrix if lower=true, refer to the upper otherwise. Only relevant when offset=0

**Details**

If *n>2*, then *A* represents a batch of square matrices on the trailing two dimensions. The extracted triangular sub-matrices are returned as an *n-1*-dimensional tensor.

The *offset* and *lower* parameters determine the triangle to be extracted:

- When *offset = 0* either the lower or upper triangle with respect to the main diagonal is extracted depending on the value of parameter *lower*.
- When *offset = k > 0* the upper triangle with respect to the k-th diagonal above the main diagonal is extracted.
- When *offset = k < 0* the lower triangle with respect to the k-th diagonal below the main diagonal is extracted.

.. note:: The operator supports float32 and float64 data types only.

**Examples**:

Single triagonal extraction $A = [[1.0, 2.0], [3.0, 4.0]]$

extractttrian($A$) = [1.0, 3.0, 4.0] extractttrian($A$, lower=False) = [1.0, 2.0, 4.0] extractttrian($A$, 1) = [2.0] extractttrian($A$, -1) = [3.0]

Batch triagonal extraction $A = [[[1.0, 2.0], [3.0, 4.0]], [[5.0, 6.0], [7.0, 8.0]]]$

extractttrian($A$) = [[[1.0, 3.0, 4.0], [5.0, 7.0, 8.0]]]

Defined in src/operator/tensor/la_op.cc:L605
Value

out The result mx.ndarray

mx.nd.linalg.gelqf

LQ factorization for general matrix. Input is a tensor *A* of dimension *n >= 2*.

Description

If *n=2*, we compute the LQ factorization (LAPACK *gelqf*, followed by *orglq*). *A* must have shape *(x, y)* with *x <= y*, and must have full rank *=x*. The LQ factorization consists of *

Arguments

A

NDArray-or-Symbol Tensor of input matrices to be factorized

Details

*A* = *L* \* *Q*

Here, *L* is lower triangular (upper triangle equal to zero) with nonzero diagonal, and *Q* is row-orthonormal, meaning that

*Q* \* *Q*\,:sup:`T`

is equal to the identity matrix of shape *(x, x)*.

If *n>2*, *gelqf* is performed separately on the trailing two dimensions for all inputs (batch mode).

Examples::

Single LQ factorization A = [[1., 2., 3.], [4., 5., 6.]] Q, L = gelqf(A) Q = [[-0.26726124, -0.53452248, -0.80178373], [0.87287156, 0.21821789, -0.43643578]] L = [[-3.74165739, 0.], [-8.55235974, 1.96396101]]

Batch LQ factorization A = [[[1., 2., 3.], [4., 5., 6.]], [[7., 8., 9.], [10., 11., 12.]]] Q, L = gelqf(A) Q = [[[[-0.26726124, -0.53452248, -0.80178373], [0.87287156, 0.21821789, -0.43643578]], [[-0.50257071, -0.57436653, -0.64616234], [0.7620735, 0.05862104, -0.64483142]]] L = [[[[-3.74165739, 0.], [-8.55235974, 1.96396101]], [[-13.92838828, 0.], [-19.09768702, 0.52758934]]]

Defined in src/operator/tensor/la_op.cc:L798

Value

out The result mx.ndarray
mx.nd.linalg.gemm performs general matrix multiplication and accumulation. Input are tensors \(A\), \(B\), \(C\), each of dimension \(n \geq 2\) and having the same shape on the leading \(n-2\) dimensions.

### Description

If \(n=2\), the BLAS3 function \(\text{gemm}\) is performed:

### Arguments

- **A**
  - NDArray-or-Symbol Tensor of input matrices
- **B**
  - NDArray-or-Symbol Tensor of input matrices
- **C**
  - NDArray-or-Symbol Tensor of input matrices
- **transpose.a**
  - boolean, optional, default=0 Multiply with transposed of first input \((A)\).
- **transpose.b**
  - boolean, optional, default=0 Multiply with transposed of second input \((B)\).
- **alpha**
  - double, optional, default=1 Scalar factor multiplied with \(A\)*\(B\).
- **beta**
  - double, optional, default=1 Scalar factor multiplied with \(C\).
- **axis**
  - int, optional, default='2' Axis corresponding to the matrix rows.

### Details

\[
\text{out} = \alpha \text{op}(A) \text{op}(B) + \beta C
\]

Here, \(\alpha\) and \(\beta\) are scalar parameters, and \(\text{op}()\) is either the identity or matrix transposition (depending on \(\text{transpose_a}\), \(\text{transpose_b}\)).

If \(n>2\), \(\text{gemm}\) is performed separately for a batch of matrices. The column indices of the matrices are given by the last dimensions of the tensors, the row indices by the axis specified with the \(axis\) parameter. By default, the trailing two dimensions will be used for matrix encoding.

For a non-default axis parameter, the operation performed is equivalent to a series of swapaxes/gemm/swapaxes calls. For example let \(A\), \(B\), \(C\) be 5 dimensional tensors. Then \(\text{gemm}(A, B, C, \text{axis}=1)\) is equivalent to the following without the overhead of the additional swapaxis operations::

\[
\begin{align*}
A1 &= \text{swapaxes}(A, \text{dim1}=1, \text{dim2}=3) \\
B1 &= \text{swapaxes}(B, \text{dim1}=1, \text{dim2}=3) \\
C &= \text{swapaxes}(C, \text{dim1}=1, \text{dim2}=3) \\
\text{out} &= \text{gemm}(A1, B1, C)
\end{align*}
\]

When the input data is of type float32 and the environment variables MXNET_CUDA_ALLOW_TENSOR_CORE and MXNET_CUDA_TENSOR_OP_MATH_ALLOW_CONVERSION are set to 1, this operator will try to use pseudo-float16 precision (float32 math with float16 I/O) precision in order to use Tensor Cores on suitable NVIDIA GPUs. This can sometimes give significant speedups.

.. note:: The operator supports float32 and float64 data types only.

### Examples::

Single matrix multiply-add \(A = [[1.0, 1.0], [1.0, 1.0]]\) \(B = [[1.0, 1.0], [1.0, 1.0], [1.0, 1.0]]\) \(C = [[1.0, 1.0, 1.0], [1.0, 1.0, 1.0, 1.0]]\) \(\text{gemm}(A, B, C, \text{transpose_b}=True, \alpha=2.0, \beta=10.0) = [[14.0, 14.0, 14.0], [14.0, 14.0, 14.0]]\)
Batch matrix multiply-add \( A = [[1.0, 1.0]], [[0.1, 0.1]] \) \( B = [[1.0, 1.0]], [[0.01]] \) \( C = [[[10.0]], [[0.01]]] \)
\[
gemm(A, B, C, transpose_b=True, alpha=2.0, beta=10.0) = [[[104.0]], [[0.14]]]
\]
Defined in src/operator/tensor/la_op.cc:L89

**Value**

out The result mx.ndarray

---

**mx.nd.linalg.gemm2**

Performs general matrix multiplication. Input are tensors *A*, *B*, each of dimension *n >= 2* and having the same shape on the leading *n-2* dimensions.

**Description**

If *n=2*, the BLAS3 function *gemm* is performed:

**Arguments**

- **A**
  NDArray-or-Symbol Tensor of input matrices
- **B**
  NDArray-or-Symbol Tensor of input matrices
- **transpose.a**
  boolean, optional, default=0 Multiply with transposed of first input (A).
- **transpose.b**
  boolean, optional, default=0 Multiply with transposed of second input (B).
- **alpha**
  double, optional, default=1 Scalar factor multiplied with A*B.
- **axis**
  int, optional, default=’-2’ Axis corresponding to the matrix row indices.

**Details**

\[ \text{out} = \alpha \cdot \text{op}(A) \cdot \text{op}(B) \]

Here \( \alpha \) is a scalar parameter and \( \text{op()} \) is either the identity or the matrix transposition (depending on \( \text{transpose}_a, \text{transpose}_b \)).

If *n>2*, *gemm* is performed separately for a batch of matrices. The column indices of the matrices are given by the last dimensions of the tensors, the row indices by the axis specified with the *axis* parameter. By default, the trailing two dimensions will be used for matrix encoding.

For a non-default axis parameter, the operation performed is equivalent to a series of swapaxes/gemm/swapaxes calls. For example let \( A^*, B^* \) be 5 dimensional tensors. Then gemm(*A*, *B*, axis=1) is equivalent to the following without the overhead of the additional swapaxis operations::

\[
A1 = \text{swapaxes}(A, \dim1=1, \dim2=3) \ B1 = \text{swapaxes}(B, \dim1=1, \dim2=3) \ C = \text{gemm2}(A1, B1) \ C = \text{swapaxis}(C, \dim1=1, \dim2=3)
\]

When the input data is of type float32 and the environment variables MXNET_CUDALIBRARY_ALLOW_TENSOR_CORE and MXNET_CUDALIBRARY_TENSOR.VERSION_OP_MATH_ALLOW_CONVERSION are set to 1, this operator will try to use pseudo-float16 precision (float32 math with float16 I/O) precision in order to use Tensor Cores on suitable NVIDIA GPUs. This can sometimes give significant speedups.

.. note:: The operator supports float32 and float64 data types only.
Examples:

Single matrix multiply $A = \begin{bmatrix} 1.0 & 1.0 \\ 1.0 & 1.0 \end{bmatrix}$ $B = \begin{bmatrix} 1.0 & 1.0 & 1.0 \\ 1.0 & 1.0 & 1.0 \end{bmatrix}$ $\text{gemm2}(A, B, \text{transpose}_b=True, \alpha=2.0) = \begin{bmatrix} 4.0 & 4.0 & 4.0 \\ 4.0 & 4.0 & 4.0 \end{bmatrix}$

Batch matrix multiply $A = \begin{bmatrix} 1.0 & 1.0 \\ 0.1 & 0.1 \end{bmatrix}$ $B = \begin{bmatrix} 1.0 & 1.0 \\ 0.1 & 0.1 \end{bmatrix}$ $\text{gemm2}(A, B, \text{transpose}_b=True, \alpha=2.0) = \begin{bmatrix} 4.0 \\ 0.04 \end{bmatrix}$

Defined in src/operator/tensor/la_op.cc:L163

Value

out The result mx.ndarray

mx.nd.linalg.inverse  
*Compute the inverse of a matrix. Input is a tensor *A* of dimension *n >= 2*. *

Description

If *n=2*, *A* is a square matrix. We compute:

Arguments

- A  
  NDArray-or-Symbol Tensor of square matrix

Details

$out = A^{-1}$

If *n>2*, *inverse* is performed separately on the trailing two dimensions for all inputs (batch mode).

.. note:: The operator supports float32 and float64 data types only.

Examples:

Single matrix inverse $A = \begin{bmatrix} 1. & 4. \\ 2. & 3. \end{bmatrix}$ $\text{inverse}(A) = \begin{bmatrix} -0.6 & 0.8 \\ 0.4 & -0.2 \end{bmatrix}$

Batch matrix inverse $A = \begin{bmatrix} 1. & 4. \\ 2. & 3. \\ 1. & 3. \\ 2. & 4. \end{bmatrix}$ $\text{inverse}(A) = \begin{bmatrix} -0.6 & 0.8 \\ 0.4 & -0.2 \\ -2. & 1.5 \\ 1. & -0.5 \end{bmatrix}$

Defined in src/operator/tensor/la_op.cc:L920

Value

out The result mx.ndarray
mx.nd.linalg.makediag

*Constructs a square matrix with the input as diagonal. Input is a tensor *A* of dimension *n >= 1*.*

**Description**

If *n=1*, then *A* represents the diagonal entries of a single square matrix. This matrix will be returned as a 2-dimensional tensor. If *n>1*, then *A* represents a batch of diagonals of square matrices. The batch of diagonal matrices will be returned as an *n+1*-dimensional tensor.

**Arguments**

- **A**
  NDArray-or-Symbol Tensor of diagonal entries
- **offset**
  int, optional, default='0' Offset of the diagonal versus the main diagonal. 0 corresponds to the main diagonal, a negative/positive value to diagonals below/above the main diagonal.

**Details**

.. note:: The operator supports float32 and float64 data types only.

Examples::

Single diagonal matrix construction A = [1.0, 2.0]
makediag(A) = [[1.0, 0.0], [0.0, 2.0]]
makediag(A, 1) = [[0.0, 1.0, 0.0], [0.0, 0.0, 2.0], [0.0, 0.0, 0.0]]
Batch diagonal matrix construction A = [[1.0, 2.0], [3.0, 4.0]]
makediag(A) = [[[1.0, 0.0], [0.0, 2.0]], [[3.0, 0.0], [0.0, 4.0]]]
Defined in src/operator/tensor/la_op.cc:L547

**Value**

out The result mx.ndarray

mx.nd.linalg.maketrian

*Constructs a square matrix with the input representing a specific triangular sub-matrix. This is basically the inverse of *linalg.extracttrian*. Input is a tensor *A* of dimension *n >= 1*.*

**Description**

If *n=1*, then *A* represents the entries of a triangular matrix which is lower triangular if *offset<0* or *offset=0*, *lower=true*. The resulting matrix is derived by first constructing the square matrix with the entries outside the triangle set to zero and then adding *offset*-times an additional diagonal with zero entries to the square matrix.
Arguments

A  NDArray-or-Symbol Tensor of triangular matrices stored as vectors
offset  int, optional, default='0' Offset of the diagonal versus the main diagonal. 0 corresponds to the main diagonal, a negative/positive value to diagonals below/above the main diagonal.
lower  boolean, optional, default=1 Refer to the lower triangular matrix if lower=true, refer to the upper otherwise. Only relevant when offset=0

Details

If *n>1*, then *A* represents a batch of triangular sub-matrices. The batch of corresponding square matrices is returned as an *n+1* dimensional tensor.

.. note:: The operator supports float32 and float64 data types only.

Examples::

Single matrix construction A = [1.0, 2.0, 3.0]
maketrian(A) = [[1.0, 0.0], [2.0, 3.0]]
maketrian(A, lower=false) = [[1.0, 2.0], [0.0, 3.0]]
maketrian(A, offset=1) = [[0.0, 1.0, 2.0], [0.0, 0.0, 3.0], [0.0, 0.0, 0.0]]
maketrian(A, offset=-1) =

Batch matrix construction A = [[1.0, 2.0, 3.0], [4.0, 5.0, 6.0]]
maketrian(A) = [[[1.0, 0.0], [2.0, 3.0]], [[4.0, 0.0], [5.0, 6.0]]]
maketrian(A, offset=1) = [[[0.0, 1.0, 2.0], [0.0, 0.0, 3.0], [0.0, 0.0, 0.0]], [[0.0, 4.0, 5.0], [0.0, 0.0, 6.0], [0.0, 0.0, 0.0]]]

Defined in src/operator/tensor/la_op.cc:L673

Value

out The result mx.ndarray

mx.nd.linalg.potrf  

Performs Cholesky factorization of a symmetric positive-definite matrix. Input is a tensor *A* of dimension *n >= 2*.

Description

If *n=2*, the Cholesky factor *B* of the symmetric, positive definite matrix *A* is computed. *B* is triangular (entries of upper or lower triangle are all zero), has positive diagonal entries, and:

Arguments

A  NDArray-or-Symbol Tensor of input matrices to be decomposed
mx.nd.linalg.potri

Performs matrix inversion from a Cholesky factorization. Input is a tensor *A* of dimension *n >= 2*.

Value

out The result mx.ndarray

mx.nd.linalg.potri

Perform matrix inversion from a Cholesky factorization. Input is a tensor *A* of dimension *n >= 2*.

Description

If *n=2*, *A* is a triangular matrix (entries of upper or lower triangle are all zero) with positive diagonal. We compute:

Arguments

A

NDArray-or-Symbol Tensor of lower triangular matrices

Details

*out* = *A*\textsuperscript{\textsuperscript{-T}} \textsuperscript{-1} if *lower* = *true*  
*out* = *A*\textsuperscript{\textsuperscript{-T}} \textsuperscript{-1} if *lower* = *false*

In other words, if *A* is the Cholesky factor of a symmetric positive definite matrix *B* (obtained by *potrf*), then

*out* = *B*\textsuperscript{-1}

If *n>2*, *potri* is performed separately on the trailing two dimensions for all inputs (batch mode).

.. note:: Use this operator only if you are certain you need the inverse of *B*, and cannot use the Cholesky factor *A* (*potrf*), together with backsubstitution (*trsm*). The latter is numerically much safer, and also cheaper.

Examples::

Single matrix inverse A = [[2.0, 0], [0.5, 2.0]]  
potri(A) = [[0.26563, -0.0625], [-0.0625, 0.25]]

Batch matrix inverse A = [[[2.0, 0], [0.5, 2.0]], [[4.0, 0], [1.0, 4.0]]]  
potri(A) = [[[0.26563, -0.0625], [-0.0625, 0.25]], [[0.06641, -0.01562], [-0.01562, 0.0625]]]

Defined in src/operator/tensor/la_op.cc:L275
mx.nd.linalg.slogdet

Compute the sign and log of the determinant of a matrix. Input is a tensor \( A \) of dimension \( n \geq 2 \).

Description

If \( n=2 \), \( A \) is a square matrix. We compute:

\[
\text{sign} = \text{sign} \left(\det(A)\right), \quad \text{logabsdet} = \log(\text{abs}(\det(A)))
\]

If \( n>2 \), \( \text{slogdet} \) is performed separately on the trailing two dimensions for all inputs (batch mode).

.. note:: The operator supports float32 and float64 data types only. .. note:: The gradient is not properly defined on sign, so the gradient of it is not backwaded. .. note:: No gradient is backwaded when \( A \) is non-invertible. Please see the docs of operator det for detail.

Examples:

Single matrix signed log determinant

\[
A = \begin{bmatrix} 2. & 3. \\ 1. & 4. \end{bmatrix}
\]

\[
\text{sign} = [1.], \quad \text{logabsdet} = [1.609438]
\]

Batch matrix signed log determinant

\[
A = \begin{bmatrix} \begin{bmatrix} 2. & 3. \end{bmatrix} & \begin{bmatrix} 1. & 4. \end{bmatrix} \\ \begin{bmatrix} 1. & 2. \end{bmatrix} & \begin{bmatrix} 2. & 4. \end{bmatrix} \\ \begin{bmatrix} 1. & 2. \end{bmatrix} & \begin{bmatrix} 4. & 3. \end{bmatrix} \end{bmatrix}
\]

\[
\text{sign} = [1., 0., -1.], \quad \text{logabsdet} = [1.609438, -\infty, 1.609438]
\]

Defined in src/operator/tensor/la_op.cc:L1034

Value

out The result mx.ndarray
**mx.nd.linalg.sumlogdiag**

*Computes the sum of the logarithms of the diagonal elements of a square matrix. Input is a tensor *A* of dimension *n >= 2*.*

**Description**

If *n=2*, *A* must be square with positive diagonal entries. We sum the natural logarithms of the diagonal elements, the result has shape (1,).

**Arguments**

- **A**: NDArray-or-Symbol, Tensor of square matrices

**Details**

If *n>2*, *sumlogdiag* is performed separately on the trailing two dimensions for all inputs (batch mode).

.. note:: The operator supports float32 and float64 data types only.

**Examples**

Single matrix reduction

\[ A = \begin{bmatrix} 1.0, 1.0 \end{bmatrix}, \begin{bmatrix} 1.0, 7.0 \end{bmatrix} \]  

\[ \text{sumlogdiag}(A) = [1.9459] \]

Batch matrix reduction

\[ A = \begin{bmatrix} \begin{bmatrix} 1.0, 1.0 \end{bmatrix}, \begin{bmatrix} 1.0, 7.0 \end{bmatrix} \end{bmatrix}, \begin{bmatrix} \begin{bmatrix} 3.0, 0 \end{bmatrix}, \begin{bmatrix} 0, 17.0 \end{bmatrix} \end{bmatrix} \]  

\[ \text{sumlogdiag}(A) = [1.9459, 3.9318] \]

Defined in src/operator/tensor/la_op.cc:L445

**Value**

- **out**: The result mx.ndarray

---

**mx.nd.linalg.syrk**

*Multiplication of matrix with its transpose. Input is a tensor *A* of dimension *n >= 2*.*

**Description**

If *n=2*, the operator performs the BLAS3 function *syrk*:

**Arguments**

- **A**: NDArray-or-Symbol, Tensor of input matrices
- **transpose**: boolean, optional, default=0 Use transpose of input matrix.
- **alpha**: double, optional, default=1 Scalar factor to be applied to the result.
Details

\[ \text{out} = \alpha \cdot A \cdot A^\top \]
if \( \text{transpose}=False \), or
\[ \text{out} = \alpha \cdot A^\top \cdot A \]
if \( \text{transpose}=True \).

If \( n>2 \), \syrk\ is performed separately on the trailing two dimensions for all inputs (batch mode).

.. note:: The operator supports float32 and float64 data types only.

Examples:

Single matrix multiply
\[ A = \begin{bmatrix} 1. & 2. & 3. \\ 4. & 5. & 6. \end{bmatrix} \]
\[
\begin{align*}
\text{syrk}(A, \alpha=1., \text{transpose}=False) &= \begin{bmatrix} 14. & 32. \\ 32. & 77. \end{bmatrix} \\
\text{syrk}(A, \alpha=1., \text{transpose}=True) &= \begin{bmatrix} 17. & 22. & 27. \\ 22. & 29. & 36. \\ 27. & 36. & 45. \end{bmatrix}
\end{align*}
\]

Batch matrix multiply
\[ A = \begin{bmatrix} \begin{bmatrix} 1. & 1. \end{bmatrix} \\ \begin{bmatrix} 0.1, 0.1 \end{bmatrix} \end{bmatrix} \]
\[
\begin{align*}
\text{syrk}(A, \alpha=2., \text{transpose}=False) &= \begin{bmatrix} 4. \\ 0.04 \end{bmatrix} \\
\end{align*}
\]

Defined in src/operator/tensor/la_op.cc:L730

Value

\text{out} The result mx.ndarray

mx.nd.linalg.trmm

Performs multiplication with a lower triangular matrix. Input are tensors \( A^*, B^* \), each of dimension \( n \geq 2 \) and having the same shape on the leading \( n-2 \) dimensions.

Description

If \( n=2 \), \( A^* \) must be triangular. The operator performs the BLAS3 function \*trmm\*:

Arguments

- \( A \) NDArray-or-Symbol Tensor of lower triangular matrices
- \( B \) NDArray-or-Symbol Tensor of matrices
- \( \text{transpose} \) boolean, optional, default=0 Use transposed of the triangular matrix
- \( \text{rightside} \) boolean, optional, default=0 Multiply triangular matrix from the right to non-triangular one.
- \( \text{lower} \) boolean, optional, default=1 True if the triangular matrix is lower triangular, false if it is upper triangular.
- \( \alpha \) double, optional, default=1 Scalar factor to be applied to the result.
mx.nd.linalg.trsm

**Details**

\[ \text{out} = \alpha \cdot \text{op}(A) \cdot B \]

if \(\text{rightside}=\text{False}\), or

\[ \text{out} = \alpha \cdot B \cdot \text{op}(A) \]

if \(\text{rightside}=\text{True}\). Here, \(\alpha\) is a scalar parameter, and \(\text{op}()\) is either the identity or the matrix transposition (depending on \(\text{transpose}\)).

If \(n>2\), \(\text{trmm}\) is performed separately on the trailing two dimensions for all inputs (batch mode).

.. note:: The operator supports float32 and float64 data types only.

**Examples:**

Single triangular matrix multiply

\[ A = \begin{bmatrix} 1.0 & 0 \\ 1.0 & 1.0 \end{bmatrix} \quad B = \begin{bmatrix} 1.0 & 1.0 & 1.0 \\ 1.0 & 1.0 & 1.0 \end{bmatrix} \]

\[ \text{trmm}(A, B, \alpha=2.0) = \begin{bmatrix} 2.0 & 2.0 & 2.0 \\ 4.0 & 4.0 & 4.0 \end{bmatrix} \]

Batch triangular matrix multiply

\[ A = \begin{bmatrix} \begin{bmatrix} 1.0 & 0 \\ 1.0 & 1.0 \end{bmatrix} \end{bmatrix}, \begin{bmatrix} 1.0 & 0 \\ 1.0 & 1.0 \end{bmatrix} \end{bmatrix} \quad B = \begin{bmatrix} \begin{bmatrix} 1.0 & 1.0 & 1.0 \\ 0.5 & 0.5 & 0.5 \end{bmatrix} \\ \begin{bmatrix} 1.0 & 1.0 & 1.0 \\ 2.0 & 2.0 & 2.0 \end{bmatrix} \end{bmatrix} \]

\[ \text{trmm}(A, B, \alpha=2.0) = \begin{bmatrix} \begin{bmatrix} 2.0 & 2.0 & 2.0 \\ 1.0 & 1.0 & 1.0 \end{bmatrix} \\ \begin{bmatrix} 2.0 & 2.0 & 2.0 \\ 2.0 & 2.0 & 2.0 \end{bmatrix} \end{bmatrix} \]

Defined in src/operator/tensor/la_op.cc:L333

**Value**

out The result mx.nd.array

mx.nd.linalg.trsm  
Solves matrix equation involving a lower triangular matrix. Input are tensors \(*A*, *B*), each of dimension \(*n >= 2* and having the same shape on the leading \(*n-2* dimensions.

**Description**

If \(n=2\), \(A\) must be triangular. The operator performs the BLAS3 function \(\text{trsm}\), solving for \(\text{out}\) in:

**Arguments**

A NDArray-or-Symbol Tensor of lower triangular matrices

B NDArray-or-Symbol Tensor of matrices

transpose boolean, optional, default=0 Use transposed of the triangular matrix

rightside boolean, optional, default=0 Multiply triangular matrix from the right to non-triangular one.

lower boolean, optional, default=1 True if the triangular matrix is lower triangular, false if it is upper triangular.

alpha double, optional, default=1 Scalar factor to be applied to the result.
**mx.nd.LinearRegressionOutput**

Computes and optimizes for squared loss during backward propagation. Just outputs “data” during forward propagation.

**Description**

If \( \hat{y}_i \) is the predicted value of the i-th sample, and \( y_i \) is the corresponding target value, then the squared loss estimated over \( n \) samples is defined as

\[
\text{SquaredLoss}(\mathbf{Y}, \hat{\mathbf{Y}}) = \frac{1}{n} \sum_{i=0}^{n-1} \| y_i - \hat{y}_i \|_2
\]

**Arguments**

- **data**: NDArray-or-Symbol Input data to the function.
- **label**: NDArray-or-Symbol Input label to the function.
- **grad.scale**: float, optional, default=1 Scale the gradient by a float factor

**Details**

\[
\text{SquaredLoss}(\mathbf{Y}, \hat{\mathbf{Y}}) = \frac{1}{n} \sum_{i=0}^{n-1} \| y_i - \hat{y}_i \|_2
\]

.. note:: Use the LinearRegressionOutput as the final output layer of a net.

The storage type of “label” can be “default” or “csr”
- LinearRegressionOutput(default, default) = default - LinearRegressionOutput(default, csr) = default

By default, gradients of this loss function are scaled by factor ‘1/m’, where m is the number of regression outputs of a training example. The parameter ‘grad_scale’ can be used to change this scale to ‘grad_scale/m’.

Defined in src/operator/regression_output.cc:L92

Value

out The result mx.ndarray

---

### **mx.nd.load**

*Load an mx.ndarray object on disk*

**Description**

Load an mx.ndarray object on disk

**Usage**

```python
mx.nd.load(filename)
```

**Arguments**

- **filename**: the filename (including the path)

**Examples**

```python
mat = mx.nd.array(1:3)
mx.nd.save(mat, 'temp.mat')
mat2 = mx.nd.load('temp.mat')
as.array(mat)
as.array(mat2)
```

---

### **mx.nd.log**

*Returns element-wise Natural logarithmic value of the input.*

**Description**

The natural logarithm is logarithm in base *e*, so that “log(exp(x)) = x”

**Arguments**

- **data**: NDArray-or-Symbol The input array.
mx.nd.log.softmax

Details

The storage type of “log” output is always dense

Defined in src/operator/tensor/elemwise_unary_op_logexp.cc:L77

Value

out The result mx.ndarray

mx.nd.log.softmax Computes the log softmax of the input. This is equivalent to computing softmax followed by log.

Description

Examples::

Arguments

data NDArray-or-Symbol The input array.
axis int, optional, default=-1 The axis along which to compute softmax.
temperature double or None, optional, default=None Temperature parameter in softmax
dtype None, 'float16', 'float32', 'float64', optional, default=None DType of the output in case this can’t be inferred. Defaults to the same as input’s dtype if not defined (dtype=None).
use.length boolean or None, optional, default=0 Whether to use the length input as a mask over the data input.

Details

>> x = mx.nd.array([1, 2, .1]) >> mx.nd.log_softmax(x).asnumpy() array([-1.41702998, -0.41702995, -2.31702995], dtype=float32)

>> x = mx.nd.array([[1, 2, .1],[.1, 2, 1]]) >> mx.nd.log_softmax(x, axis=0).asnumpy() array([[-3.0954247, 0.0, 0.0], [0.0, -3.0954247, 0.0]], dtype=float32)

Value

out The result mx.ndarray
mx.nd.log10

Returns element-wise Base-10 logarithmic value of the input.

**Description**

“10**log10(x) = x”

**Arguments**

- **data** NDArray-or-Symbol The input array.

**Details**

The storage type of “log10” output is always dense

Defined in src/operator/tensor/elemwise_unary_op_logexp.cc:L94

**Value**

- **out** The result mx.ndarray

mx.nd.log1p

Returns element-wise “log(1 + x)” value of the input.

**Description**

This function is more accurate than “log(1 + x)” for small “x” so that :math:`1+x\approx 1`

**Arguments**

- **data** NDArray-or-Symbol The input array.

**Details**

The storage type of “log1p” output depends upon the input storage type:

- log1p(default) = default - log1p(row_sparse) = row_sparse - log1p(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_logexp.cc:L199

**Value**

- **out** The result mx.ndarray
mx.nd.log2

Returns element-wise Base-2 logarithmic value of the input.

Description

“2**log2(x) = x”

Arguments

data NDArray-or-Symbol The input array.

Details

The storage type of “log2“ output is always dense

Defined in src/operator/tensor/elemwise_unary_op_logexp.cc:L106

Value

out The result mx.ndarray

mx.nd.logical.not

Returns the result of logical NOT (!) function

Description

Example: logical_not([-2., 0., 1.]) = [0., 1., 0.]

Arguments

data NDArray-or-Symbol The input array.

Value

out The result mx.ndarray
mx.nd.LogisticRegressionOutput

Applies a logistic function to the input.

Description

The logistic function, also known as the sigmoid function, is computed as $\frac{1}{1+\exp(-\textbf{x})}$.

Arguments

- **data**: NDArray-or-Symbol
  Input data to the function.
- **label**: NDArray-or-Symbol
  Input label to the function.
- **grad.scale**: float, optional, default=1
  Scale the gradient by a float factor

Details

Commonly, the sigmoid is used to squash the real-valued output of a linear model $wTx+b$ into the [0,1] range so that it can be interpreted as a probability. It is suitable for binary classification or probability prediction tasks.

.. note:: Use the LogisticRegressionOutput as the final output layer of a net.

The storage type of “label” can be “default“ or “csr“

- LogisticRegressionOutput(default, default) = default
- LogisticRegressionOutput(default, csr) = default

The loss function used is the Binary Cross Entropy Loss:

$-(y\log(p) + (1 - y)\log(1 - p))$

Where ‘y’ is the ground truth probability of positive outcome for a given example, and ‘p’ the probability predicted by the model. By default, gradients of this loss function are scaled by factor ‘1/m’, where m is the number of regression outputs of a training example. The parameter ‘grad_scale’ can be used to change this scale to ‘grad_scale/m’.

Defined in src/operator/regression_output.cc:L152

Value

- **out**: The result mx.ndarray
**mx.nd.LRN**

Applies local response normalization to the input.

**Description**

The local response normalization layer performs "lateral inhibition" by normalizing over local input regions.

**Arguments**

- **data**
  NDArray-or-Symbol Input data to LRN
- **alpha**
  float, optional, default=9.99999975e-05 The variance scaling parameter :math:`\alpha` in the LRN expression.
- **beta**
  float, optional, default=0.75 The power parameter :math:`\beta` in the LRN expression.
- **knorm**
  float, optional, default=2 The parameter :math:`k` in the LRN expression.
- **nsize**
  int (non-negative), required normalization window width in elements.

**Details**

If :math:`a_{x,y}^i` is the activity of a neuron computed by applying kernel :math:`i` at position :math:`(x, y)` and then applying the ReLU nonlinearity, the response-normalized activity :math:`b_{x,y}^i` is given by the expression:

\[
  b_{x,y}^i = \frac{a_{x,y}^i}{k + \frac{\alpha n}{\sum_{j=\max(0, i-n/2)}^{\min(N-1, i+n/2)} (a_{x,y}^j)^2}}^{\beta}
\]

where the sum runs over :math:`n` "adjacent" kernel maps at the same spatial position, and :math:`N` is the total number of kernels in the layer.

Defined in `src/operator/nn/lrn.cc:L158`

**Value**

```
out The result mx.ndarray
```

---

**mx.nd.MAERegressionOutput**

Computes mean absolute error of the input.

**Description**

MAE is a risk metric corresponding to the expected value of the absolute error.
mx.nd.make.loss

Arguments

- **data**: NDArray-or-Symbol Input data to the function.
- **label**: NDArray-or-Symbol Input label to the function.
- **grad.scale**: float, optional, default=1 Scale the gradient by a float factor

Details

If \( \hat{y}_i \) is the predicted value of the i-th sample, and \( y_i \) is the corresponding target value, then the mean absolute error (MAE) estimated over \( n \) samples is defined as:

\[
\text{MAE}(\textbf{Y}, \hat{\textbf{Y}}) = \frac{1}{n} \sum_{i=0}^{n-1} \lVert \textbf{y}_i - \hat{\textbf{y}}_i \rVert_1
\]

.. note:: Use the MAERegressionOutput as the final output layer of a net.

The storage type of “label” can be “default” or “csr”:
- MAERegressionOutput(default, default) = default
- MAERegressionOutput(default, csr) = default

By default, gradients of this loss function are scaled by factor ‘1/m’, where m is the number of regression outputs of a training example. The parameter ‘grad_scale’ can be used to change this scale to ‘grad_scale/m’.

Defined in src/operator/regression_output.cc:L120

Value

- **out**: The result mx.ndarray

mx.nd.make.loss Make your own loss function in network construction.

Description

This operator accepts a customized loss function symbol as a terminal loss and the symbol should be an operator with no backward dependency. The output of this function is the gradient of loss with respect to the input data.

Arguments

- **data**: NDArray-or-Symbol The input array.

Details

For example, if you are a making a cross entropy loss function. Assume “out” is the predicted output and “label” is the true label, then the cross entropy can be defined as:

\[
\text{cross_entropy} = \text{label} \times \log(\text{out}) + (1 - \text{label}) \times \log(1 - \text{out}) \text{ loss = make_loss(cross_entropy)}
\]

We will need to use “make_loss” when we are creating our own loss function or we want to combine multiple loss functions. Also we may want to stop some variables’ gradients from backpropagation. See more detail in “BlockGrad” or “stop_gradient”.

mx.nd.make.ndarray
The storage type of “make_loss” output depends upon the input storage type:
- make_loss(default) = default - make_loss(row_sparse) = row_sparse

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L358

Value

out The result mx.ndarray

---

**mx.nd.MakeLoss**

*Make your own loss function in network construction.*

**Description**

This operator accepts a customized loss function symbol as a terminal loss and the symbol should be an operator with no backward dependency. The output of this function is the gradient of loss with respect to the input data.

**Arguments**

- **data**: NDArray-or-Symbol Input array.
- **grad.scale**: float, optional, default=1 Gradient scale as a supplement to unary and binary operators.
- **valid.thresh**: float, optional, default=0 clip each element in the array to 0 when it is less than “valid.thresh”. This is used when “normalization” is set to “valid”.
- **normalization**: ‘batch’, ‘null’, ‘valid’.optional, default=’null’ If this is set to null, the output gradient will not be normalized. If this is set to batch, the output gradient will be divided by the batch size. If this is set to valid, the output gradient will be divided by the number of valid input elements.

**Details**

For example, if you are a making a cross entropy loss function. Assume “out” is the predicted output and “label” is the true label, then the cross entropy can be defined as:

cross_entropy = label * log(out) + (1 - label) * log(1 - out) loss = MakeLoss(cross_entropy)

We will need to use “MakeLoss” when we are creating our own loss function or we want to combine multiple loss functions. Also we may want to stop some variables’ gradients from backpropagation. See more detail in “BlockGrad” or “stop_gradient”.

In addition, we can give a scale to the loss by setting “grad_scale”, so that the gradient of the loss will be rescaled in the backpropagation.

.. note:: This operator should be used as a Symbol instead of NDArray.

Defined in src/operator/make_loss.cc:L71

Value

out The result mx.ndarray

---
mx.nd.max

*Computes the max of array elements over given axes.*

**Description**

Defined in src/operator/tensor/./broadcast_reduce_op.h:L32

**Arguments**

- **data**: NDArray-or-Symbol The input
- **axis**: Shape or None, optional, default=None The axis or axes along which to perform the reduction.
  - The default, ‘axis=()’, will compute over all elements into a scalar array with shape ‘(1,)’.
  - If ‘axis’ is int, a reduction is performed on a particular axis.
  - If ‘axis’ is a tuple of ints, a reduction is performed on all the axes specified in the tuple.
  - If ‘include’ is true, reduction will be performed on the axes that are NOT in axis instead.
  - Negative values means indexing from right to left.
- **keepdims**: boolean, optional, default=0 If this is set to ‘True’, the reduced axes are left in the result as dimension with size one.
- **exclude**: boolean, optional, default=0 Whether to perform reduction on axis that are NOT in axis instead.

**Value**

- **out**: The result mx.ndarray

mx.nd.max.axis

*Computes the max of array elements over given axes.*

**Description**

Defined in src/operator/tensor/./broadcast_reduce_op.h:L32

**Arguments**

- **data**: NDArray-or-Symbol The input
mx.nd.mean

axis Shape or None, optional, default=None The axis or axes along which to perform the reduction.
The default, ‘axis=()’, will compute over all elements into a scalar array with shape ‘(1,)’.
If ‘axis’ is int, a reduction is performed on a particular axis.
If ‘axis’ is a tuple of ints, a reduction is performed on all the axes specified in the tuple.
If ‘exclude’ is true, reduction will be performed on the axes that are NOT in axis instead.
Negative values means indexing from right to left.

keepdims boolean, optional, default=0 If this is set to ‘True’, the reduced axes are left in the result as dimension with size one.

exclude boolean, optional, default=0 Whether to perform reduction on axis that are NOT in axis instead.

Value
out The result mx.ndarray

mx.nd.mean Computes the mean of array elements over given axes.

Description
Defined in src/operator/tensor/./broadcast_reduce_op.h:L84

Arguments
data NDArray-or-Symbol The input
axis Shape or None, optional, default=None The axis or axes along which to perform the reduction.
The default, ‘axis=()’, will compute over all elements into a scalar array with shape ‘(1,)’.
If ‘axis’ is int, a reduction is performed on a particular axis.
If ‘axis’ is a tuple of ints, a reduction is performed on all the axes specified in the tuple.
If ‘exclude’ is true, reduction will be performed on the axes that are NOT in axis instead.
Negative values means indexing from right to left.
keepdims boolean, optional, default=0 If this is set to ‘True’, the reduced axes are left in the result as dimension with size one.
exclude boolean, optional, default=0 Whether to perform reduction on axis that are NOT in axis instead.

Value
out The result mx.ndarray
mx.nd.min

Computes the min of array elements over given axes.

Description

Defined in src/operator/tensor/broadcast_reduce_op.h:L47

Arguments

data NDArray-or-Symbol The input
axis Shape or None, optional, default=None The axis or axes along which to perform the reduction.
The default, ‘axis=()’, will compute over all elements into a scalar array with shape ‘(1,)’.
If ‘axis’ is int, a reduction is performed on a particular axis.
If ‘axis’ is a tuple of ints, a reduction is performed on all the axes specified in the tuple.
If ‘exclude’ is true, reduction will be performed on the axes that are NOT in axis instead.
Negative values means indexing from right to left.
keepdims boolean, optional, default=0 If this is set to ‘True’, the reduced axes are left in the result as dimension with size one.
exclude boolean, optional, default=0 Whether to perform reduction on axis that are NOT in axis instead.

Value

out The result mx.ndarray

mx.nd.min.axis

Computes the min of array elements over given axes.

Description

Defined in src/operator/tensor/broadcast_reduce_op.h:L47

Arguments

data NDArray-or-Symbol The input
mx.nd.moments

**axis**
Shape or None, optional, default=None
The axis or axes along which to perform the reduction.
The default, `axis=()`, will compute over all elements into a scalar array with shape `(1,)`.
If `axis` is int, a reduction is performed on a particular axis.
If `axis` is a tuple of ints, a reduction is performed on all the axes specified in the tuple.
If `exclude` is true, reduction will be performed on the axes that are NOT in `axis` instead.
Negative values means indexing from right to left.

**keepdims**
boolean, optional, default=0
If this is set to `True`, the reduced axes are left in the result as dimension with size one.

**exclude**
boolean, optional, default=0
Whether to perform reduction on axis that are NOT in `axis` instead.

**Value**

`out` The result mx.ndarray

---

**Description**
The mean and variance are calculated by aggregating the contents of data across axes. If x is 1-D and axes = [0] this is just the mean and variance of a vector.

**Arguments**

- **data**
  NDArray-or-Symbol
  Input ndarray

- **axes**
  Shape or None, optional, default=None
  Array of ints. Axes along which to compute mean and variance.

- **keepdims**
  boolean, optional, default=0
  produce moments with the same dimensionality as the input.

**Details**

Example:
```
x = [[1, 2, 3], [4, 5, 6]] mean, var = moments(data=x, axes=[0]) mean = [2.5, 3.5, 4.5] var = [2.25, 2.25, 2.25] mean, var = moments(data=x, axes=[1]) mean = [2.0, 5.0] var = [0.66666667, 0.66666667] mean, var = moments(data=x, axis=[0, 1]) mean = [3.5] var = [2.9166667]
```
Defined in src/operator/nn/moments.cc:L54

**Value**

`out` The result mx.ndarray
Mixed Precision version of Phase I of lamb update it performs the following operations and returns g:

**Description**

**Arguments**

- `weight` (NDArray-or-Symbol) Weight
- `grad` (NDArray-or-Symbol) Gradient
- `mean` (NDArray-or-Symbol) Moving mean
- `var` (NDArray-or-Symbol) Moving variance
- `weight32` (NDArray-or-Symbol) Weight32
- `beta1` (float, optional, default=0.899999976) The decay rate for the 1st moment estimates.
- `beta2` (float, optional, default=0.999000013) The decay rate for the 2nd moment estimates.
- `epsilon` (float, optional, default=9.99999997e-07) A small constant for numerical stability.
- `t` (int, required) Index update count.
- `bias.correction` (boolean, optional, default=1) Whether to use bias correction.
- `wd` (float, required) Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
- `rescale.grad` (float, optional, default=1) Rescale gradient to grad = rescale_grad*grad.
- `clip.gradient` (float, optional, default=-1) Clip gradient to the range of [-clip_gradient, clip_gradient] If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).

**Details**

\[
\begin{align*}
\text{grad32} &= \text{grad}(\text{float16}) \times \text{rescale_grad} \quad \text{if (grad < -clip_gradient) then grad = -clip_gradient; otherwise grad = clip_gradient} \\
\text{mean} &= \beta_1 \times \text{mean} + (1 - \beta_1) \times \text{grad}; \quad \text{variance} = \beta_2 \times \text{variance} + (1 - \beta_2) \times \text{grad}^2; \\
\text{if (bias_correction) then } \text{mean} &= \text{mean} / (1 - \beta_1^t); \quad \text{var} = \text{var} / (1 - \beta_2^t); \quad \text{g} = \text{mean} / (\text{var}^{(1/2)} + \text{epsilon}) + \text{weight32}; \quad \text{else } g = \text{mean} / (\text{var_data}^{(1/2)} + \text{epsilon}) + \text{weight32}; \\
\end{align*}

- **lazy.update**: boolean, optional, default=1 If true, lazy updates are applied if gradient’s stype is row_sparse and both weight and momentum have the same stype

Value

- **out**: The result mx.ndarray

**mx.nd.mp.sgd.update**  
Updater function for multi-precision sgd optimizer

Description

Updater function for multi-precision sgd optimizer

Arguments

- **weight**: NDArray-or-Symbol Weight
- **grad**: NDArray-or-Symbol gradient
- **weight32**: NDArray-or-Symbol Weight32
- **lr**: float, required Learning rate
- **wd**: float, optional, default=0 Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
- **rescale.grad**: float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
- **clip.gradient**: float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient] If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).
- **lazy.update**: boolean, optional, default=1 If true, lazy updates are applied if gradient’s stype is row_sparse.
**mx.nd.multi.all.finite**

Check if all the float numbers in all the arrays are finite (used for AMP)

**Description**

Defined in src/operator/contrib/all_finite.cc:L133

**Arguments**

- **data**: NDArray-or-Symbol[] Arrays
- **num.arrays**: int, optional, default='1' Number of arrays.
- **init.output**: boolean, optional, default=1 Initialize output to 1.

**Value**

out The result mx.ndarray

---

**mx.nd.multi.lars**

Compute the LARS coefficients of multiple weights and grads from their sums of square

**Description**

Defined in src/operator/contrib/multi_lars.cc:L37

**Arguments**

- **lrs**: NDArray-or-Symbol Learning rates to scale by LARS coefficient
- **weights.sum.sq**: NDArray-or-Symbol sum of square of weights arrays
- **grads.sum.sq**: NDArray-or-Symbol sum of square of gradients arrays
- **wds**: NDArray-or-Symbol weight decays
- **eta**: float, required LARS eta
- **eps**: float, required LARS eps
- **rescale.grad**: float, optional, default=1 Gradient rescaling factor

**Value**

out The result mx.ndarray
Momentum update function for multi-precision Stochastic Gradient Descent (SGD) optimizer.

**Description**

Momentum update has better convergence rates on neural networks. Mathematically it looks like below:

\[
v_1 = \alpha \nabla J(W_0) \ 

v_t = \gamma v_{t-1} - \alpha \nabla J(W_{t-1}) \\
W_t = W_{t-1} + v_t
\]

It updates the weights using:

\[
v = \text{momentum} \times v - \text{learning_rate} \times \text{gradient} \ 

weight += v
\]

Where the parameter “momentum” is the decay rate of momentum estimates at each epoch.

**Arguments**

- **data**
  NDArray-or-Symbol[] Weights

- **lr0**
  tuple of <float>, required Learning rates.

- **wds**
  tuple of <float>, required Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.

- **momentum**
  float, optional, default=0 The decay rate of momentum estimates at each epoch.

- **rescale.grad**
  float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.

- **clip.gradient**
  float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient] If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).

- **num.weights**
  int, optional, default='1’ Number of updated weights.

**Details**

\[
v_1 = \alpha \nabla J(W_0) \\
v_t = \gamma v_{t-1} - \alpha \nabla J(W_{t-1}) \\
W_t = W_{t-1} + v_t
\]

**Value**

out The result mx.nd.array
mx.nd.multi.mp.sgd.update

Update function for multi-precision Stochastic Gradient Descent (SDG) optimizer.

Description

It updates the weights using::

Arguments

data
NDArray-or-Symbol[] Weights

lrs
tuple of <float>, required Learning rates.

wds
tuple of <float>, required Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.

data
tuple of <float>, required Learning rates.

rescale.grad
float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.

clip.gradient
float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient]

If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).

num.weights
int, optional, default='1’ Number of updated weights.

Details

weight = weight - learning_rate * (gradient + wd * weight)

Defined in src/operator/optimizer_op.cc:L417

Value

out The result mx.ndarray

mx.nd.multi.sgd.mom.update

Momentum update function for Stochastic Gradient Descent (SGD) optimizer.

Description

Momentum update has better convergence rates on neural networks. Mathematically it looks like below:
Arguments

data NDArray-or-Symbol[] Weights, gradients and momentum
lrs tuple of <float>, required Learning rates.
wd tuple of <float>, required Weight decay augments the objective function with
a regularization term that penalizes large weights. The penalty scales with the
square of the magnitude of each weight.
momentum float, optional, default=0 The decay rate of momentum estimates at each epoch.
rescale.grad float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
clip.gradient float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient]
num.weights int, optional, default='1' Number of updated weights.

Details

.. math::
\begin{align*}
v_1 &= \alpha \nabla J(W_0) \\
v_t &= \gamma v_{t-1} - \alpha \nabla J(W_{t-1}) \\
W_t &= W_{t-1} + v_t
\end{align*}

It updates the weights using::

\begin{align*}
v &= \text{momentum} \cdot v - \text{learning_rate} \cdot \text{gradient}
weight += v
\end{align*}

Where the parameter “momentum“ is the decay rate of momentum estimates at each epoch.

Defined in src/operator/optimizer_op.cc:L374

Value

out The result mx.ndarray
**clip.gradient** float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient]
If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).

**num.weights** int, optional, default='1' Number of updated weights.

**Details**

weight = weight - learning_rate * (gradient + wd * weight)

Defined in src/operator/optimizer_op.cc:L329

**Details**

Where $\eta$ is the learning rate of the optimizer $\gamma$ is the decay rate of the momentum estimate $v_t$ is the update vector at time step $t$ $W_t$ is the weight vector at time step $t$

Defined in src/operator/optimizer_op.cc:L726

**Value**

out The result mx.nd.array

---

**mx.nd.nanprod**

*Computes the product of array elements over given axes treating Not a Numbers ("NaN") as one.*

**Description**

Computes the product of array elements over given axes treating Not a Numbers ("NaN") as one.

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>NDArray-or-Symbol The input</td>
</tr>
<tr>
<td>axis</td>
<td>Shape or None, optional, default=None The axis or axes along which to perform the reduction. The default, ‘axis=()’, will compute over all elements into a scalar array with shape ‘(1,)’. If ‘axis’ is int, a reduction is performed on a particular axis. If ‘axis’ is a tuple of ints, a reduction is performed on all the axes specified in the tuple. If ‘exclude’ is true, reduction will be performed on the axes that are NOT in axis instead. Negative values means indexing from right to left.</td>
</tr>
</tbody>
</table>

Computes the sum of array elements over given axes treating Not a Numbers ("NaN") as zero.

Arguments

- **data**: NDArray-or-Symbol The input
- **axis**: Shape or None, optional, default=None The axis or axes along which to perform the reduction.
  The default, ‘axis=()’, will compute over all elements into a scalar array with shape ‘(1,)’.
  If ‘axis’ is int, a reduction is performed on a particular axis.
  If ‘axis’ is a tuple of ints, a reduction is performed on all the axes specified in the tuple.
  If ‘exclude’ is true, reduction will be performed on the axes that are NOT in axis instead.
  Negative values means indexing from right to left.
- **keepdims**: boolean, optional, default=0 If this is set to ‘True’, the reduced axes are left in the result as dimension with size one.
- **exclude**: boolean, optional, default=0 Whether to perform reduction on axis that are NOT in axis instead.

Details

Defined in src/operator/tensor/broadcast_reduce_sum_value.cc:L102

Value

out The result mx.ndarray
mx.nd.negative

**Numerical negative of the argument, element-wise.**

**Description**

The storage type of “negative” output depends upon the input storage type:

**Arguments**

- **data**
  - NDArray-or-Symbol: The input array.

**Details**

- negative(default) = default - negative(row_sparse) = row_sparse - negative(csr) = csr

**Value**

- out: The result mx.ndarray

mx.nd.norm

**Computes the norm on an NDArray.**

**Description**

This operator computes the norm on an NDArray with the specified axis, depending on the value of the ord parameter. By default, it computes the L2 norm on the entire array. Currently only ord=2 supports sparse ndarrays.

**Arguments**

- **data**
  - NDArray-or-Symbol: The input
- **ord**
  - int, optional, default='2': Order of the norm. Currently ord=1 and ord=2 is supported.
- **axis**
  - Shape or None, optional, default=None: The axis or axes along which to perform the reduction. The default, ‘axis=()’, will compute over all elements into a scalar array with shape ‘(1,)’. If ‘axis’ is int, a reduction is performed on a particular axis. If ‘axis’ is a 2-tuple, it specifies the axes that hold 2-D matrices, and the matrix norms of these matrices are computed.
- **out.dtype**
- **keepdims**
  - boolean, optional, default=0: If this is set to ‘True’, the reduced axis is left in the result as dimension with size one.
Details

Examples:

\[
x = \begin{bmatrix}
[1, 2], [3, 4], [2, 2], [5, 6] \\
\end{bmatrix}
\]

\[
\text{norm}(x, \text{ord}=2, \text{axis}=1) = \begin{bmatrix}
3.1622777, 4.472136, 5.3851647, 6.3245554 \\
\end{bmatrix}
\]

\[
\text{norm}(x, \text{ord}=1, \text{axis}=1) = \begin{bmatrix}
4., 6., 7., 8. \\
\end{bmatrix}
\]

\[
\text{rsp} = x.\text{cast\_storage}\left(\text{row\_sparse}\right)
\]

\[
\text{norm}(\text{rsp}) = [5.47722578]
\]

\[
\text{csr} = x.\text{cast\_storage}\left(\text{csr}\right)
\]

\[
\text{norm}(\text{csr}) = [5.47722578]
\]

Defined in src/operator/tensor/broadcast_reduce_norm_value.cc:L89

Value

out The result mx.nd.array

mx.nd.normal

Draw random samples from a normal (Gaussian) distribution.

Description

.. note:: The existing alias “normal” is deprecated.

Arguments

- **loc**
  - float, optional, default=0 Mean of the distribution.

- **scale**
  - float, optional, default=1 Standard deviation of the distribution.

- **shape**
  - Shape(tuple), optional, default=None Shape of the output.

- **ctx**
  - string, optional, default=” Context of output, in format [cpu|gpu|cpu_pinned](n). Only used for imperative calls.

- **dtype**
  - ‘None’, ‘float16’, ‘float32’, ‘float64’, optional, default=’None’ DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).

Details

Samples are distributed according to a normal distribution parametrized by *loc* (mean) and *scale* (standard deviation).

Example:

\[
\text{normal}(\text{loc}=0, \text{scale}=1, \text{shape}=(2,2)) = \begin{bmatrix}
1.89171135, -1.16881478, -1.23474145, 1.55807114 \\
\end{bmatrix}
\]

Defined in src/operator/random/sample_op.cc:L113

Value

out The result mx.nd.array
mx.nd.one.hot

Returns a one-hot array.

Description

The locations represented by ‘indices’ take value ‘on_value’, while all other locations take value ‘off_value’.

Arguments

- **indices**: NDArray-or-Symbol array of locations where to set on_value
- **depth**: int, required Depth of the one hot dimension.
- **on.value**: double, optional, default=1 The value assigned to the locations represented by indices.
- **off.value**: double, optional, default=0 The value assigned to the locations not represented by indices.

Details

‘one_hot’ operation with ‘indices’ of shape “(i0, i1)” and ‘depth’ of “d” would result in an output array of shape “(i0, i1, d)” with:

\[
\text{output}[i, j, :] = \text{off_value} \quad \text{output}[i, j, \text{indices}[i, j]] = \text{on_value}
\]

Examples:

- one_hot([1,0,2,0], 3) = [[ 0. 1. 0.] [ 1. 0. 0.] [ 0. 0. 1.] [ 1. 0. 0.]]
- one_hot([1,0,2,0], 3, on_value=8, off_value=1, dtype='int32') = [[1 8 1] [8 1 1] [1 1 8] [8 1 1]]
- one_hot([[1,0],[1,0],[2,0]], 3) = [[[ 0. 1. 0.] [ 0. 0. 1.]] [[ 0. 0. 1.] [ 1. 0. 0.]]]

Defined in src/operator/tensor/indexing_op.cc:L883

Value

- out The result mx.nd.array
mx.nd.ones

Generate an mx.ndarray object with ones

Description
Generate an mx.ndarray object with ones

Usage
mx.nd.ones(shape, ctx = NULL)

Arguments
shape
the dimension of the mx.ndarray
ctx
optional The context device of the array. mx.ctx.default() will be used in default.

Examples
mat = mx.nd.ones(10)
as.array(mat)
mat2 = mx.nd.ones(c(5,5))
as.array(mat)
mat3 = mx.nd.ones(c(3,3,3))
as.array(mat3)

mx.nd.ones.like
Return an array of ones with the same shape and type as the input array.

Description
Examples::

Arguments
data
NDArray-or-Symbol The input

Details
x = [[ 0., 0., 0.], [ 0., 0., 0.]]
ones_like(x) = [[ 1., 1., 1.], [ 1., 1., 1.]]

Value
out The result mx.ndarray
mx.nd.Pad

**Pads an input array with a constant or edge values of the array.**

**Description**

.. note:: ‘Pad’ is deprecated. Use ‘pad’ instead.

**Arguments**

- **data**: NDArray-or-Symbol An n-dimensional input array.
- **mode**: 'constant', 'edge', 'reflect', required Padding type to use. "constant" pads with 'constant_value' "edge" pads using the edge values of the input array "reflect" pads by reflecting values with respect to the edges.
- **pad.width**: Shape(tuple), required Widths of the padding regions applied to the edges of each axis. It is a tuple of integer padding widths for each axis of the format “(before_1, after_1, ... , before_N, after_N)”. It should be of length “2*N” where “N” is the number of dimensions of the array. This is equivalent to pad_width in numpy.pad, but flattened.
- **constant.value**: double, optional, default=0 The value used for padding when ‘mode’ is "constant".

**Details**

.. note:: Current implementation only supports 4D and 5D input arrays with padding applied only on axes 1, 2 and 3. Expects axes 4 and 5 in ‘pad_width’ to be zero.

This operation pads an input array with either a ‘constant_value’ or edge values along each axis of the input array. The amount of padding is specified by ‘pad_width’.

‘pad_width’ is a tuple of integer padding widths for each axis of the format “(before_1, after_1, ... , before_N, after_N)”. The ‘pad_width’ should be of length “2*N” where “N” is the number of dimensions of the array.

For dimension “N” of the input array, “before_N” and “after_N” indicates how many values to add before and after the elements of the array along dimension “N”. The widths of the higher two dimensions “before_1”, “after_1”, “before_2”, “after_2” must be 0.

Example::

```python
x = [[[ 1.  2.  3.]]
     [[ 7.  8.  9.]]
     [[11. 12. 13.]]
     [[17. 18. 19.]]]
pad(x,mode="edge", pad_width=(0,0,0,1,1,1)) =

[[[ 1.  1.  2.  3.  3.  3.  4.  4.  5.  6.  6.]]
 [[ 7.  7.  8.  9.  9.  9. 10. 10. 11. 12. 12.]]
 [[ 7.  7.  8.  9. 10. 10. 11. 11. 11. 12. 13.]]
 [[ 7.  7.  8.  9. 10. 10. 11. 11. 11. 12. 13.]]
 [[ 7.  7.  8.  9. 10. 10. 11. 11. 11. 12. 13.]]
 [[ 7.  7.  8.  9. 10. 10. 11. 11. 11. 12. 13.]]
```
mx.nd.pad

pad(x, mode="constant", constant_value=0, pad_width=(0,0,0,1,1,1,1)) =
[[[  0.  0.  0.  0.  0.] [  0.  1.  2.  3.  0.] [  0.  4.  5.  6.  0.] [  0.  0.  0.  0.  0.]]
[[  0.  0.  0.  0.  0.] [  0.  7.  8.  9.  0.] [  0. 10. 11. 12.  0.] [  0.  0.  0.  0.  0.]]
[[  0.  0.  0.  0.  0.] [  0. 11. 12. 13.  0.] [  0. 14. 15. 16.  0.] [  0.  0.  0.  0.  0.]]
[[  0.  0.  0.  0.  0.] [  0. 17. 18. 19.  0.] [  0. 20. 21. 22.  0.] [  0.  0.  0.  0.  0.]]]

Defined in src/operator/pad.cc:L766

Value

out The result mx.ndarray

mx.nd.pad  Pads an input array with a constant or edge values of the array.

Description

.. note:: 'Pad' is deprecated. Use 'pad' instead.

Arguments

data NDArray-or-Symbol An n-dimensional input array.

mode 'constant', 'edge', 'reflect', required Padding type to use. "constant" pads with
'constant_value' "edge" pads using the edge values of the input array "reflect"
pads by reflecting values with respect to the edges.

pad.width Shape(tuple), required Widths of the padding regions applied to the edges of
each axis. It is a tuple of integer padding widths for each axis of the format "(be-
fore_1, after_1, ... , before_N, after_N)". It should be of length "2*N" where
"N" is the number of dimensions of the array. This is equivalent to pad_width in
numpy.pad, but flattened.

constant.value double, optional, default=0 The value used for padding when 'mode' is "con-
stant".

Details

.. note:: Current implementation only supports 4D and 5D input arrays with padding applied only
on axes 1, 2 and 3. Expects axes 4 and 5 in 'pad_width' to be zero.

This operation pads an input array with either a 'constant_value' or edge values along each axis of
the input array. The amount of padding is specified by 'pad_width'.

'pad_width' is a tuple of integer padding widths for each axis of the format "(before_1, after_1, ...
, before_N, after_N)". The 'pad_width' should be of length "2*N" where "N" is the number of
dimensions of the array.
For dimension "N" of the input array, "before_N" and "after_N" indicates how many values to add before and after the elements of the array along dimension "N". The widths of the higher two dimensions "before_1", "after_1", "before_2", "after_2" must be 0.

Example::

```python
x = [[[ 1.  2.  3.] [ 4.  5.  6.]]
    [[ 7.  8.  9.] [10. 11. 12.]]
    [[[11. 12. 13.] [14. 15. 16.]]
    [[17. 18. 19.] [20. 21. 22.]]]]
```

```python
pad(x, mode="edge", pad_width=(0,0,0,0,1,1,1,1)) =
```

```python
[[[ 1.  1.  2.  3.  3.] [ 1.  1.  2.  3.  3.] [ 4.  4.  5.  6.  6.] [ 4.  4.  5.  6.  6.]]
 [ 7.  7.  8.  9.  9.] [ 7.  7.  8.  9.  9.] [10. 10. 10. 0. 12.] [10. 10. 10. 12. 12.]]
```

```python
pad(x, mode="constant", constant_value=0, pad_width=(0,0,0,0,1,1,1,1)) =
```

```python
[[[ 0.  0.  0.  0.  0.] [ 0.  1.  2.  3.  0.] [ 0.  4.  5.  6.  0.] [ 0.  0.  0.  0.  0.]]
 [ 0.  0.  0.  0.  0.] [ 0.  7.  8.  9.  0.] [ 0.  10. 11. 12.  0.] [ 0.  0.  0.  0.  0.]]
[[ 0.  0.  0.  0.  0.] [ 0.  11. 12. 13.  0.] [ 0.  14. 15. 16.  0.] [ 0.  0.  0.  0.  0.]]
 [[ 0.  0.  0.  0.  0.] [ 0.  17. 18. 19.  0.] [ 0.  20. 21. 22.  0.] [ 0.  0.  0.  0.  0.]]]
```

Defined in src/operator/pad.cc:L766

Value

out The result mx.ndarray

mx.nd.pick

Picks elements from an input array according to the input indices along the given axis.

Description

Given an input array of shape "(d0, d1)" and indices of shape "(i0,)", the result will be an output array of shape "(i0,)" with::

Arguments

data NDArray-or-Symbol The input array

index NDArray-or-Symbol The index array

axis int or None, optional, default=-1 int or None. The axis to picking the elements. Negative values means indexing from right to left. If is 'None', the elements in the index w.r.t the flattened input will be picked.
mx.nd.Pooling

**Details**

\[
\text{output}[i] = \text{input}[i, \text{indices}[i]]
\]

By default, if any index mentioned is too large, it is replaced by the index that addresses the last element along an axis (the 'clip' mode).

This function supports n-dimensional input and (n-1)-dimensional indices arrays.

**Examples:**

\[
x = [[ 1., 2.], [ 3., 4.], [ 5., 6.]]
\]

// picks elements with specified indices along axis 0
\[
pick(x, y=[0,1], 0) = [ 1., 4.]
\]

// picks elements with specified indices along axis 1
\[
pick(x, y=[0,1,0], 1) = [ 1., 4., 5.]
\]

// picks elements with specified indices along axis 1 using 'wrap' mode // to place indicies that would normally be out of bounds
\[
pick(x, y=[2,-1,-2], 1, \text{mode}='\text{wrap}') = [ 1., 4., 5.]
\]

\[
y = [[ 1.], [ 0.], [ 2.]]
\]

// picks elements with specified indices along axis 1 and dims are maintained
\[
pick(x, y, 1, \text{keepdims}=\text{True}) = [[ 2.], [ 3.], [ 6.]]
\]

Defined in src/operator/tensor/broadcast_reduce_op_index.cc:L151

**Value**

out The result mx.ndarray

---

**mx.nd.Pooling**

*Performs pooling on the input.*

**Description**

The shapes for 1-D pooling are

**Arguments**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>NDArray-or-Symbol</td>
<td>Input data to the pooling operator.</td>
</tr>
<tr>
<td>kernel</td>
<td>Shape(tuple), optional, default=[]</td>
<td>Pooling kernel size: (y, x) or (d, y, x)</td>
</tr>
<tr>
<td>pool.type</td>
<td>‘avg’, ’lp’, ’max’, ’sum’, optional, default=’max’</td>
<td>Pooling type to be applied.</td>
</tr>
<tr>
<td>global.pool</td>
<td>boolean, optional, default=0</td>
<td>Ignore kernel size, do global pooling based on current input feature map.</td>
</tr>
</tbody>
</table>
cudnn.off boolean, optional, default=0 Turn off cudnn pooling and use MXNet pooling operator.

pooling.convention 'full', 'same', 'valid', optional, default='valid' Pooling convention to be applied.

stride Shape(tuple), optional, default=[] Stride: for pooling (y, x) or (d, y, x). Defaults to 1 for each dimension.

pad Shape(tuple), optional, default=[] Pad for pooling: (y, x) or (d, y, x). Defaults to no padding.

p.value int or None, optional, default='None' Value of p for Lp pooling, can be 1 or 2, required for Lp Pooling.

count.include.pad boolean or None, optional, default=None Only used for AvgPool, specify whether to count padding elements for average calculation. For example, with a 5*5 kernel on a 3*3 corner of an image, the sum of the 9 valid elements will be divided by 25 if this is set to true, or it will be divided by 9 if this is set to false. Defaults to true.

layout None, 'NCDHW', 'NCHW', 'NCW', 'NDHWC', 'NHWC', 'NWC', optional, default='None' Set layout for input and output. Empty for default layout: NCW for 1d, NCHW for 2d and NCDHW for 3d.

Details

- **data** and **out**: *(batch_size, channel, width)* (NCW layout) or *(batch_size, width, channel)* (NWC layout),
  The shapes for 2-D pooling are
  - **data** and **out**: *(batch_size, channel, height, width)* (NCHW layout) or *(batch_size, height, width, channel)* (NHWC layout),
  out_height = f(height, kernel[0], pad[0], stride[0]) out_width = f(width, kernel[1], pad[1], stride[1])
  The definition of *f* depends on “pooling_convention”, which has two options:
  - **valid** (default)::
    f(x, k, p, s) = floor((x+2*p-k)/s)+1
  - **full***, which is compatible with Caffe::
    f(x, k, p, s) = ceil((x+2*p-k)/s)+1

When “global_pool” is set to be true, then global pooling is performed. It will reset “kernel=(height, width)” and set the appropriate padding to 0.

Three pooling options are supported by “pool_type”: 
- **avg**: average pooling - **max**: max pooling - **sum**: sum pooling - **lp**: Lp pooling

For 3-D pooling, an additional *depth* dimension is added before *height*. Namely the input data and output will have shape *(batch_size, channel, depth, height, width)* (NCDHW layout) or *(batch_size, depth, height, width, channel)* (NDHWC layout).

Notes on Lp pooling:
Lp pooling was first introduced by this paper: https://arxiv.org/pdf/1204.3968.pdf. L-1 pooling is simply sum pooling, while L-inf pooling is simply max pooling. We can see that Lp pooling stands between those two, in practice the most common value for p is 2.

For each window “X”, the mathematical expression for Lp pooling is:

\[ f(X) = \sqrt[p]{\sum_{x} x^p} \]

Defined in src/operator/nn/pooling.cc:L417

**Value**

out The result mx.ndarray

---

mx.nd.Pooling.v1

This operator is DEPRECATED. Perform pooling on the input.

**Description**

The shapes for 2-D pooling is

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>NDArray-or-Symbol Input data to the pooling operator.</td>
</tr>
<tr>
<td>kernel</td>
<td>Shape(tuple), optional, default=[] pooling kernel size: (y, x) or (d, y, x)</td>
</tr>
<tr>
<td>pool.type</td>
<td>'avg', 'max', 'sum',optional, default='max' Pooling type to be applied.</td>
</tr>
<tr>
<td>global.pool</td>
<td>boolean, optional, default=0 Ignore kernel size, do global pooling based on current input feature map.</td>
</tr>
<tr>
<td>pooling.convention</td>
<td>'full', 'valid',optional, default='valid' Pooling convention to be applied.</td>
</tr>
<tr>
<td>stride</td>
<td>Shape(tuple), optional, default=[] stride: for pooling (y, x) or (d, y, x)</td>
</tr>
<tr>
<td>pad</td>
<td>Shape(tuple), optional, default=[] pad for pooling: (y, x) or (d, y, x)</td>
</tr>
</tbody>
</table>

**Details**

- **data**: *(batch_size, channel, height, width)* - **out**: *(batch_size, num_filter, out_height, out_width)*, with:

  out_height = f(height, kernel[0], pad[0], stride[0]) out_width = f(width, kernel[1], pad[1], stride[1])

  The definition of *f* depends on "pooling_convention", which has two options:
  - **valid** (default):
    
    \[ f(x, k, p, s) = \text{floor}((x+2*p-k)/s)+1 \]
  - **full**, which is compatible with Caffe:
    
    \[ f(x, k, p, s) = \text{ceil}((x+2*p-k)/s)+1 \]

  But “global_pool” is set to be true, then do a global pooling, namely reset “kernel=(height, width)“.

  Three pooling options are supported by “pool_type”:
**mx.nd.preloaded.multi.mp.sgd.mom.update**

- **avg**: average pooling - **max**: max pooling - **sum**: sum pooling

1-D pooling is a special case of 2-D pooling with *weight=1* and *kernel[1]=1*.

For 3-D pooling, an additional *depth* dimension is added before *height*. Namely the input data will have shape *(batch_size, channel, depth, height, width)*.

Defined in src/operator/pooling_v1.cc:L104

**Value**

out The result mx.ndarray

---

**mx.nd.preloaded.multi.mp.sgd.mom.update**

*Momentum update function for multi-precision Stochastic Gradient Descent (SGD) optimizer.*

---

**Description**

Momentum update has better convergence rates on neural networks. Mathematically it looks like below:

**Arguments**

data NDArray-or-Symbol[] Weights, gradients, momentums, learning rates and weight decays

momentum float, optional, default=0 The decay rate of momentum estimates at each epoch.

rescale.grad float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.

clip.gradient float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient]. If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).

num.weights int, optional, default='1' Number of updated weights.

**Details**

.. math::

\begin{align*}
    v_{t+1} &= \alpha \nabla J(W_t) \\
    v_t &= \gamma v_{t-1} - \alpha \nabla J(W_{t-1}) \\
    W_t &= W_{t-1} + v_t
\end{align*}

It updates the weights using::

\begin{align*}
    v &= \text{momentum} \times v - \text{learning_rate} \times \text{gradient weight} + \text{v}
\end{align*}

Where the parameter “momentum” is the decay rate of momentum estimates at each epoch.

Defined in src/operator/contrib/preloaded_multi_sgd.cc:L200

**Value**

out The result mx.ndarray
mx.nd.preloaded.multi.mp.sgd.update

Update function for multi-precision Stochastic Gradient Descent (SDG) optimizer.

Description

It updates the weights using::

Arguments

data: NDArray-or-Symbol[] Weights, gradients, learning rates and weight decays
rescale.grad: float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
clip.gradient: float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient] If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).
num.weights: int, optional, default='1' Number of updated weights.

Details

weight = weight - learning_rate * (gradient + wd * weight)

Defined in src/operator/contrib/preloaded_multi_sgd.cc:L140

Value

out The result mx.ndarray

mx.nd.preloaded.multi.sgd.mom.update

Momentum update function for Stochastic Gradient Descent (SGD) optimizer.

Description

Momentum update has better convergence rates on neural networks. Mathematically it looks like below:
Arguments

data NDArray-or-Symbol[] Weights, gradients, momentum, learning rates and weight decays
momentum float, optional, default=0 The decay rate of momentum estimates at each epoch.
rescale.grad float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
clip.gradient float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient]
num.weights int, optional, default=1 Number of updated weights.

Details

\begin{align}
    v_{t+1} &= \alpha \nabla J(W_0) \\
    v_t &= \gamma v_{t-1} - \alpha \nabla J(W_{t-1}) \\
    W_t &= W_{t-1} + v_t
\end{align}

It updates the weights using::

\begin{align}
    v &= \text{momentum} \cdot v - \text{learning_rate} \cdot \text{gradient} \\
    \text{weight} &= \text{weight} - \text{learning_rate} \cdot (\text{gradient} + \text{wd} \cdot \text{weight})
\end{align}

Defined in src/operator/contrib/preloaded_multi_sgd.cc:L91

Value

out The result mx.ndarray
mx.nd.prod

Value

out The result mx.ndarray

mx.nd.prod

Computes the product of array elements over given axes.

Description

Defined in src/operator/tensor./broadcast_reduce_op.h:L31

Arguments

data NDArray-or-Symbol The input
axis Shape or None, optional, default=None The axis or axes along which to perform the reduction.
The default, ‘axis=()’, will compute over all elements into a scalar array with shape ‘(1,)’.
If ‘axis’ is int, a reduction is performed on a particular axis.
If ‘axis’ is a tuple of ints, a reduction is performed on all the axes specified in the tuple.
If ‘exclude’ is true, reduction will be performed on the axes that are NOT in axis instead.
Negative values means indexing from right to left.
keepdims boolean, optional, default=0 If this is set to ‘True’, the reduced axes are left in the result as dimension with size one.
exclude boolean, optional, default=0 Whether to perform reduction on axis that are NOT in axis instead.

Value

out The result mx.ndarray

mx.nd.radians

Converts each element of the input array from degrees to radians.

Description

.. math:: \text{radians([0, 90, 180, 270, 360])} = [0, \pi/2, \pi, 3\pi/2, 2\pi]

Arguments

data NDArray-or-Symbol The input array.
Details
The storage type of “radians“ output depends upon the input storage type:
- radians(default) = default - radians(row_sparse) = row_sparse - radians(csr) = csr
Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L351

Value
out The result mx.ndarray

mx.nd.random.exponential

Draw random samples from an exponential distribution.

Description
Samples are distributed according to an exponential distribution parametrized by *lambda* (rate).

Arguments
lam float, optional, default=1 Lambda parameter (rate) of the exponential distribution.
shape Shape(tuple), optional, default=None Shape of the output.
ctx string, optional, default=" Context of output, in format [cpu|gpu|cpu_pinned](n). Only used for imperative calls.
dtype 'None', 'float16', 'float32', 'float64',optional, default='None' DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).

Details
Example::

exponential(lam=4, shape=(2,2)) = [[ 0.0097189 , 0.08999364], [ 0.04146638, 0.31715935]]
Defined in src/operator/random/sample_op.cc:L137

Value
out The result mx.ndarray
mx.nd.random.gamma

Draw random samples from a gamma distribution.

Description

Samples are distributed according to a gamma distribution parametrized by *alpha* (shape) and *beta* (scale).

Arguments

- alpha: float, optional, default=1 Alpha parameter (shape) of the gamma distribution.
- beta: float, optional, default=1 Beta parameter (scale) of the gamma distribution.
- shape: Shape(tuple), optional, default=None Shape of the output.
- ctx: string, optional, default="" Context of output, in format [cpu|gpu|cpu_pinned](n). Only used for imperative calls.
- dtype: 'None', 'float16', 'float32', 'float64', optional, default='None' Dtype of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).

Details

Example::

gamma(alpha=9, beta=0.5, shape=(2,2)) = [[ 7.10486984, 3.37695289], [ 3.91697288, 3.65933681]]

Defined in src/operator/random/sample_op.cc:L125

Value

out The result mx.ndarray

mx.nd.random.generalized.negative.binomial

Draw random samples from a generalized negative binomial distribution.

Description

Samples are distributed according to a generalized negative binomial distribution parametrized by *mu* (mean) and *alpha* (dispersion). *alpha* is defined as *1/k* where *k* is the failure limit of the number of unsuccessful experiments (generalized to real numbers). Samples will always be returned as a floating point data type.
Arguments

- **mu**: float, optional, default=1 Mean of the negative binomial distribution.
- **alpha**: float, optional, default=1 Alpha (dispersion) parameter of the negative binomial distribution.
- **shape**: Shape(tuple), optional, default=None Shape of the output.
- **ctx**: string, optional, default=’’ Context of output, in format [cpu|gpu|cpu_pinned](n). Only used for imperative calls.
- **dtype**: ’None’, ’float16’, ’float32’, ’float64’,optional, default=’None’ DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).

Details

Example::

    generalized_negative_binomial(mu=2.0, alpha=0.3, shape=(2,2)) = [[2., 1.], [6., 4.]]

Defined in src/operator/random/sample_op.cc:L179

Value

out The result mx.ndarray

mx.nd.random.negative.binomial

*Draw random samples from a negative binomial distribution.*

Description

Samples are distributed according to a negative binomial distribution parametrized by \(k\) (limit of unsuccessful experiments) and \(p\) (failure probability in each experiment). Samples will always be returned as a floating point data type.

Arguments

- **k**: int, optional, default=’1’ Limit of unsuccessful experiments.
- **p**: float, optional, default=1 Failure probability in each experiment.
- **shape**: Shape(tuple), optional, default=None Shape of the output.
- **ctx**: string, optional, default=’’ Context of output, in format [cpu|gpu|cpu_pinned](n). Only used for imperative calls.
- **dtype**: ‘None’, ‘float16’, ‘float32’, ‘float64’,optional, default=’None’ DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).

Details

Example::

    negative_binomial(k=3, p=0.4, shape=(2,2)) = [[4., 7.], [2., 5.]]

Defined in src/operator/random/sample_op.cc:L164
mx.nd.random.normal

Value

out The result mx.ndarray

mx.nd.random.normal  Draw random samples from a normal (Gaussian) distribution.

Description

.. note:: The existing alias “normal” is deprecated.

Arguments

- **loc** float, optional, default=0 Mean of the distribution.
- **scale** float, optional, default=1 Standard deviation of the distribution.
- **shape** Shape(tuple), optional, default=None Shape of the output.
- **ctx** string, optional, default="Context of output, in format [cpu|gpu|cpu_pinned](n). Only used for imperative calls.
- **dtype** 'None', 'float16', 'float32', 'float64', optional, default='None' DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).

Details

Samples are distributed according to a normal distribution parametrized by *loc* (mean) and *scale* (standard deviation).

Example::

normal(loc=0, scale=1, shape=(2,2)) = [[ 1.89171135, -1.16881478], [-1.23474145, 1.55807114]]

Defined in src/operator/random/sample_op.cc:L113

Value

out The result mx.ndarray
mx.nd.random.pdf.dirichlet

Computes the value of the PDF of *sample* of Dirichlet distributions with parameter *alpha*.

Description

The shape of *alpha* must match the leftmost subshape of *sample*. That is, *sample* can have the same shape as *alpha*, in which case the output contains one density per distribution, or *sample* can be a tensor of tensors with that shape, in which case the output is a tensor of densities such that the densities at index *i* in the output are given by the samples at index *i* in *sample* parameterized by the value of *alpha* at index *i*.

Arguments

- **sample**: NDArray-or-Symbol. Samples from the distributions.
- **alpha**: NDArray-or-Symbol. Concentration parameters of the distributions.
- **is.log**: boolean, optional, default=0. If set, compute the density of the log-probability instead of the probability.

Details

Examples:

```python
random_pdf_dirichlet(sample=[[1,2],[2,3],[3,4]], alpha=[2.5, 2.5]) = [38.413498, 199.60245, 564.56085]
sample = [[[1, 2, 3], [10, 20, 30], [100, 200, 300]], [[0.1, 0.2, 0.3], [0.01, 0.02, 0.03], [0.001, 0.002, 0.003]]]
random_pdf_dirichlet(sample=sample, alpha=[0.1, 0.4, 0.9]) = [[2.3257459e-02, 5.8420084e-04, 1.4674458e-05], [9.2589635e-01, 3.6860607e+01, 1.4674468e+03]]
```

Defined in src/operator/random/pdf_op.cc:L316

Value

- **out**: The result mx.ndarray

mx.nd.random.pdf.exponential

Computes the value of the PDF of *sample* of exponential distributions with parameters *lam* (rate).
**Description**

The shape of *lam* must match the leftmost subshape of *sample*. That is, *sample* can have the same shape as *lam*, in which case the output contains one density per distribution, or *sample* can be a tensor of tensors with that shape, in which case the output is a tensor of densities such that the densities at index *i* in the output are given by the samples at index *i* in *sample* parameterized by the value of *lam* at index *i*.

**Arguments**

- **sample**
  - NDArray-or-Symbol
  - Samples from the distributions.

- **lam**
  - NDArray-or-Symbol
  - Lambda (rate) parameters of the distributions.

- **is.log**
  - boolean, optional, default=0
  - If set, compute the density of the log-probability instead of the probability.

**Details**

Examples:

```python
random_pdf_exponential(sample=[[1, 2, 3]], lam=[1]) = [[0.36787945, 0.13533528, 0.04978707]]
```

```python
sample = [[1,2,3], [1,2,3], [1,2,3]]
random_pdf_exponential(sample=sample, lam=[1.0, 0.5, 0.25]) = [[0.36787945, 0.13533528, 0.04978707],
[0.30326533, 0.18393973, 0.11156508], [0.1947002, 0.15163267, 0.11809164]]
```

Defined in src/operator/random/pdf_op.cc:L305

**Value**

- **out**
  - The result mx.ndarray
Arguments

- `sample`  :  NDArray-or-Symbol  Samples from the distributions.
- `alpha`   :  NDArray-or-Symbol  Alpha (shape) parameters of the distributions.
- `is.log`  :  boolean, optional, default=0  If set, compute the density of the log-probability instead of the probability.
- `beta`    :  NDArray-or-Symbol  Beta (scale) parameters of the distributions.

Details

Examples::

```
random_pdf_gamma(sample=[[1,2,3,4,5]], alpha=[5], beta=[1]) = [[0.01532831, 0.09022352, 0.16803136, 0.19536681, 0.17546739]]

sample = [[1, 2, 3, 4, 5], [2, 3, 4, 5, 6], [3, 4, 5, 6, 7]]
random_pdf_gamma(sample=sample, alpha=[5,6,7], beta=[1,1,1]) = [[0.01532831, 0.09022352, 0.16803136, 0.19536681, 0.17546739], [0.03608941, 0.10081882, 0.15629345, 0.17546739, 0.16062315], [0.05040941, 0.10419563, 0.14622283, 0.16062315, 0.14900276]]
```

Defined in src/operator/random/pdf_op.cc:L303

Value

- `out`  :  The result mx.ndarray

mx.nd.random.pdf.generalized.negative.binomial

Computes the value of the PDF of `sample` of generalized negative binomial distributions with parameters `mu` (mean) and `alpha` (dispersion). This can be understood as a reparameterization of the negative binomial, where `k` = 1 / `alpha` and `p` = 1 / (`mu` \* `alpha` + 1).

Description

`mu` and `alpha` must have the same shape, which must match the leftmost subshape of `sample`. That is, `sample` can have the same shape as `mu` and `alpha`, in which case the output contains one density per distribution, or `sample` can be a tensor of tensors with that shape, in which case the output is a tensor of densities such that the densities at index `i` in the output are given by the samples at index `i` in `sample` parameterized by the values of `mu` and `alpha` at index `i`.

Arguments

- `sample`  :  NDArray-or-Symbol  Samples from the distributions.
- `mu`      :  NDArray-or-Symbol  Means of the distributions.
- `is.log`  :  boolean, optional, default=0  If set, compute the density of the log-probability instead of the probability.
- `alpha`   :  NDArray-or-Symbol  Alpha (dispersion) parameters of the distributions.
Details

Examples::

random_pdf_generalized_negative_binomial(sample=[[1, 2, 3, 4]], alpha=[1], mu=[1]) = [[0.25, 0.125, 0.0625, 0.03125]]
sample=[[1,2,3,4],[1,2,3,4]] random_pdf_generalized_negative_binomial(sample=sample, alpha=[1, 0.6666], mu=[1, 1.5]) = [[0.25, 0.125, 0.0625, 0.03125 ], [0.26517063, 0.16573331, 0.09667706, 0.05437994]]

Defined in src/operator/random/pdf_op.cc:L314

Value

out The result mx.ndarray

mx.nd.random.pdf.negative.binomial

Computes the value of the PDF of samples of negative binomial distributions with parameters *k* (failure limit) and *p* (failure probability).

Description

*k* and *p* must have the same shape, which must match the leftmost subshape of *sample*. That is, *sample* can have the same shape as *k* and *p*, in which case the output contains one density per distribution, or *sample* can be a tensor of tensors with that shape, in which case the output is a tensor of densities such that the densities at index *i* in the output are given by the samples at index *i* in *sample* parameterized by the values of *k* and *p* at index *i*.

Arguments

sample NDArray-or-Symbol Samples from the distributions.
k NDArray-or-Symbol Limits of unsuccessful experiments.
is.log boolean, optional, default=0 If set, compute the density of the log-probability instead of the probability.
p NDArray-or-Symbol Failure probabilities in each experiment.

Details

Examples::

random_pdf_negative_binomial(sample=[[1,2,3,4]], k=[1], p=[0.5]) = [[0.25, 0.125, 0.0625, 0.03125]]

# Note that k may be real-valued
sample=[[1,2,3,4],[1,2,3,4]] random_pdf_negative_binomial(sample=sample, k=[1, 1.5], p=[0.5, 0.5]) = [[0.25, 0.125, 0.0625, 0.03125 ], [0.26516506, 0.16572815, 0.09667476, 0.05437956]]

Defined in src/operator/random/pdf_op.cc:L310
mx.nd.random.pdf.normal

Computes the value of the PDF of *sample* of normal distributions with parameters *mu* (mean) and *sigma* (standard deviation).

**Description**

*mu* and *sigma* must have the same shape, which must match the leftmost subshape of *sample*. That is, *sample* can have the same shape as *mu* and *sigma*, in which case the output contains one density per distribution, or *sample* can be a tensor of tensors with that shape, in which case the output is a tensor of densities such that the densities at index *i* in the output are given by the samples at index *i* in *sample* parameterized by the values of *mu* and *sigma* at index *i*.

**Arguments**

- **sample**: NDArray-or-Symbol Samples from the distributions.
- **mu**: NDArray-or-Symbol Means of the distributions.
- **is.log**: boolean, optional, default=0 If set, compute the density of the log-probability instead of the probability.
- **sigma**: NDArray-or-Symbol Standard deviations of the distributions.

**Details**

Examples:

```python
sample = [[-2, -1, 0, 1, 2]] random_pdf_normal(sample=sample, mu=[0], sigma=[1]) = [[0.05399097, 0.24197073, 0.3989423, 0.24197073, 0.05399097]]
random_pdf_normal(sample=sample*2, mu=[0,0], sigma=[1,2]) = [[0.05399097, 0.24197073, 0.3989423, 0.24197073, 0.05399097], [0.12098537, 0.17603266, 0.19947115, 0.17603266, 0.12098537]]
```

Defined in src/operator/random/pdf_op.cc:L300

**Value**

- **out**: The result mx.ndarray
Computes the value of the PDF of *sample* of Poisson distributions with parameters *lam* (rate).

**Description**

The shape of *lam* must match the leftmost subshape of *sample*. That is, *sample* can have the same shape as *lam*, in which case the output contains one density per distribution, or *sample* can be a tensor of tensors with that shape, in which case the output is a tensor of densities such that the densities at index *i* in the output are given by the samples at index *i* in *sample* parameterized by the value of *lam* at index *i*.

**Arguments**

- **sample**: NDArray-or-Symbol Samples from the distributions.
- **lam**: NDArray-or-Symbol Lambda (rate) parameters of the distributions.
- **is.log**: boolean, optional, default=0 If set, compute the density of the log-probability instead of the probability.

**Details**

Examples::

```python
random_pdf_poisson(sample=[[0,1,2,3]], lam=[1]) = [[0.36787945, 0.36787945, 0.18393973, 0.06131324]]
```

Default in src/operator/random/pdf_op.cc:L307

**Value**

- **out**: The result mx.ndarray

---

Computes the value of the PDF of *sample* of uniform distributions on the intervals given by *[low,high)*.

**Description**

*low* and *high* must have the same shape, which must match the leftmost subshape of *sample*. That is, *sample* can have the same shape as *low* and *high*, in which case the output contains one density per distribution, or *sample* can be a tensor of tensors with that shape, in which case the output is a tensor of densities such that the densities at index *i* in the output are given by the samples at index *i* in *sample* parameterized by the values of *low* and *high* at index *i*.
Arguments

- **sample**: NDArray-or-Symbol Samples from the distributions.
- **low**: NDArray-or-Symbol Lower bounds of the distributions.
- **is.log**: boolean, optional, default=0 If set, compute the density of the log-probability instead of the probability.
- **high**: NDArray-or-Symbol Upper bounds of the distributions.

Details

Examples:

```python
random_pdf_uniform(sample=[[1,2,3,4]], low=[0], high=[10]) = [0.1, 0.1, 0.1, 0.1]
sample = [[[1. 2. 3], [1. 2. 3]], [[1. 2. 3], [1. 2. 3]]] low = [[0. 0. 0.], [0. 0. 0.]] high = [[5. 10], [15. 20]] random_pdf_uniform(sample=sample, low=low, high=high) = [[0.2, 0.2, 0.2], [0.1, 0.1, 0.1]], [[0.06667, 0.06667, 0.06667], [0.05, 0.05, 0.05]]
```

Defined in src/operator/random/pdf_op.cc:L298

Value

- **out**: The result mx.ndarray

mx.nd.random.poisson

`mx.nd.random.poisson` Draw random samples from a Poisson distribution.

Description

Samples are distributed according to a Poisson distribution parametrized by *lambda* (rate). Samples will always be returned as a floating point data type.

Arguments

- **lam**: float, optional, default=1 Lambda parameter (rate) of the Poisson distribution.
- **shape**: Shape(tuple), optional, default=None Shape of the output.
- **ctx**: string, optional, default="" Context of output, in format [cpu|gpu|cpu_pinned](n). Only used for imperative calls.
- **dtype**: 'None', 'float16', 'float32', 'float64', optional, default='None' Dtype of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).

Details

Example:

```python
poisson(lam=4, shape=(2,2)) = [[5., 2.], [4., 6.]]
```

Defined in src/operator/random/sample_op.cc:L150

Value

- **out**: The result mx.ndarray
mx.nd.random.randint

Draw random samples from a discrete uniform distribution.

Description

Samples are uniformly distributed over the half-open interval \( *[\text{low}, \text{high})* \) (includes \( \text{low} \), but excludes \( \text{high} \)).

Arguments

- **low**: long, required Lower bound of the distribution.
- **high**: long, required Upper bound of the distribution.
- **shape**: Shape(tuple), optional, default=None Shape of the output.
- **ctx**: string, optional, default=" Context of output, in format [cpu|gpus:cpu_pinned](n). Only used for imperative calls.
- **dtype**: 'None', 'int32', 'int64',optional, default='None' DType of the output in case this can’t be inferred. Defaults to int32 if not defined (dtype=None).

Details

Example::

    randint(low=0, high=5, shape=(2,2)) = [[ 0, 2], [ 3, 1]]

Defined in src/operator/random/sample_op.cc:L194

Value

out The result mx.ndarray

mx.nd.random.uniform

Draw random samples from a uniform distribution.

Description

.. note:: The existing alias “uniform” is deprecated.

Arguments

- **low**: float, optional, default=0 Lower bound of the distribution.
- **high**: float, optional, default=1 Upper bound of the distribution.
- **shape**: Shape(tuple), optional, default=None Shape of the output.
- **ctx**: string, optional, default=" Context of output, in format [cpu|gpus:cpu_pinned](n). Only used for imperative calls.
- **dtype**: 'None', 'float16', 'float32', 'float64',optional, default='None' DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).
mx.nd.ravel.multi.index

**Details**

Samples are uniformly distributed over the half-open interval *(low, high)* (includes *low*, but excludes *high*).

Example:

```
uniform(low=0, high=1, shape=(2,2)) = [[ 0.60276335, 0.85794562], [ 0.54488319, 0.84725171]]
```

Defined in src/operator/random/sample_op.cc:L96

**Value**

- out The result mx.ndarray

---

mx.nd.ravel.multi.index

*Converts a batch of index arrays into an array of flat indices. The operator follows numpy conventions so a single multi index is given by a column of the input matrix. The leading dimension may be left unspecified by using -1 as placeholder.*

---

**Description**

Examples:

```
A = [[3,6,6],[4,5,1]] ravel(A, shape=(7,6)) = [22,41,37] ravel(A, shape=(-1,6)) = [22,41,37]
```

**Arguments**

- **data**: NDArray-or-Symbol Batch of multi-indices
- **shape**: Shape(tuple), optional, default=None Shape of the array into which the multi-indices apply.

**Details**

Defined in src/operator/tensor/ravel.cc:L42

**Value**

- out The result mx.ndarray
**mx.nd.rcbrt**

*Returns element-wise inverse cube-root value of the input.*

Description

.. math:: \text{rcbrt}(x) = \frac{1}{\sqrt[3]{x}}

Arguments

- **data**  
  NDArray-or-Symbol The input array.

Details

Example:

rcbrt([1.8, -125]) = [1.0, 0.5, -0.2]

Defined in `src/operator/tensor/elemwise_unary_op_pow.cc:L323`

Value

- **out** The result mx.ndarray

**mx.nd.reciprocal**

*Returns the reciprocal of the argument, element-wise.*

Description

Calculates \(1/x\).

Arguments

- **data**  
  NDArray-or-Symbol The input array.

Details

Example:

reciprocal([-2, 1, 3, 1.6, 0.2]) = [-0.5, 1.0, 0.33333334, 0.625, 5.0]

Defined in `src/operator/tensor/elemwise_unary_op_pow.cc:L43`

Value

- **out** The result mx.ndarray
**mx.nd.relu**

*Computes rectified linear activation.*

**Description**

\[
\text{ReLU}(\text{features}) = \max(\text{features}, 0)
\]

**Arguments**

- **data**: NDArray-or-Symbol The input array.

**Details**

The storage type of “relu” output depends upon the input storage type:
- relu(default) = default - relu(row_sparse) = row_sparse - relu(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L85

**Value**

- **out**: The result mx.ndarray

---

**mx.nd.repeat**

*Repeats elements of an array. By default, “repeat“ flattens the input array into 1-D and then repeats the elements.*

\[
x = [[ 1, 2], [ 3, 4]] \text{ repeat}(x, \text{ repeats}=2) = [ 1., 1., 2., 2., 3., 3., 4., 4.]
\]

The parameter “axis“ specifies the axis along which to perform repeat:

\[
\text{repeat}(x, \text{ repeats}=2, \text{ axis}=1) = [[ 1., 1., 2., 2.], [ 3., 3., 4., 4.]]
\]

Defined in src/operator/tensor/matrix_op.cc:L744

**Arguments**

- **data**: NDArray-or-Symbol Input data array
- **repeats**: int, required The number of repetitions for each element.
- **axis**: int or None, optional, default='None' The axis along which to repeat values. The negative numbers are interpreted counting from the backward. By default, use the flattened input array, and return a flat output array.

**Value**

- **out**: The result mx.ndarray
**Description**

Defined in `src/operator/contrib/reset_arrays.cc:L36`

**Arguments**

- **data**: NDArray-or-Symbol[] Arrays
- **num.arrays**: int, required number of input arrays.

**Value**

- **out**: The result mx.ndarray
mx.nd.Reshape

Reshapes the input array. 

.. note:: “Reshape“ is deprecated, use “reshape“ Given an array and a shape, this function returns a copy of the array in the new shape. The shape is a tuple of integers such as (2,3,4). The size of the new shape should be same as the size of the input array. Example:: reshape([1,2,3,4], shape=(2,2)) = [[1,2], [3,4]] Some dimensions of the shape can take special values from the set 0, -1, -2, -3, -4. The significance of each is explained below: - "0" copy this dimension from the input to the output shape. Example:: - input shape = (2,3,4), shape = (4,0,2), output shape = (4,3,2) - input shape = (2,3,4), shape = (2,0,0), output shape = (2,3,4) - "-1" infers the dimension of the output shape by using the remainder of the input dimensions keeping the size of the new array same as that of the input array. At most one dimension of shape can be -1. Example:: - input shape = (2,3,4), shape = (6,1,-1), output shape = (6,1,4) - input shape = (2,3,4), shape = (3,-1,8), output shape = (3,1,8) - input shape = (2,3,4), shape=-(-1,), output shape = (24,) - "-2" copy all/remainder of the input dimensions to the output shape. Example:: - input shape = (2,3,4), shape = (-2,), output shape = (2,3,4) - input shape = (2,3,4), shape = (2,-2), output shape = (2,3,4) - input shape = (2,3,4), shape = (-2,1,1), output shape = (2,3,4,1,1) - "-3" use the product of two consecutive dimensions of the input shape as the output dimension. Example:: - input shape = (2,3,4), shape = (-3,4), output shape = (6,4) - input shape = (2,3,4), shape = (-3,4), output shape = (6,4) - input shape = (2,3,4,5), shape = (-3,-3), output shape = (6,20) - input shape = (2,3,4), shape = (0,-3), output shape = (2,12) - input shape = (2,3,4), shape = (-3,-2), output shape = (6,4) - "-4“ split one dimension of the input into two dimensions passed subsequent to -4 in shape (can contain -1). Example:: - input shape = (2,3,4), shape = (-4,1,2,-2), output shape = (1,2,3,4) - input shape = (2,3,4), shape = (2,-4,-1,3,-2), output shape = (2,1,3,4) If the argument ‘reverse‘ is set to 1, then the special values are inferred from right to left. Example:: - without reverse=1, for input shape = (10,5,4), shape = (-1,0), output shape would be (40,5) - with reverse=1, output shape will be (50,4).

Description

Defined in src/operator/tensor/matrix_op.cc:L175

Arguments

data NDArray-or-Symbol Input data to reshape.

shape Shape(tuple), optional, default=[] The target shape

reverse boolean, optional, default=0 If true then the special values are inferred from right to left

target.shape Shape(tuple), optional, default=[] (Deprecated! Use “shape“ instead.) Target new shape. One and only one dim can be 0, in which case it will be inferred from the rest of dims
Reshapes the input array. .. note:: “Reshape“ is deprecated, use “reshape“
Given an array and a shape, this function returns a copy
of the array in the new shape. The shape is a tuple of integers such
as (2,3,4). The size of the new shape should be same as the size of
the input array. Example:: reshape([1,2,3,4], shape=(2,2)) = [[1,2],
[3,4]] Some dimensions of the shape can take special values from the
set 0, -1, -2, -3, -4. The significance of each is explained below: - “0”
copy this dimension from the input to the output shape. Example::
- input shape = (2,3,4), shape = (4,0,2), output shape = (4,3,2) - input
shape = (2,3,4), shape = (2,0,0), output shape = (2,3,4) - “-1” infers
the dimension of the output shape by using the remainder of the input
dimensions keeping the size of the new array same as that of the input
array. At most one dimension of shape can be -1. Example:: - input
shape = (2,3,4), shape = (6,1,-1), output shape = (6,1,4) - input
shape = (2,3,4), shape = (3,-1,8), output shape = (3,1,8) - input shape =
(2,3,4), shape =(-1,), output shape = (24,) - “-2” copy all/remainder
of the input dimensions to the output shape. Example:: - input shape
= (2,3,4), shape = (-2,), output shape = (2,3,4) - input shape = (2,3,4),
shape = (2,-2), output shape = (2,3,4) - input shape = (-2,1,1), output shape
= (3,2,4) - input shape = (2,3,4), shape = (0,-3), output shape = (2,12) - input
shape = (2,3,4), shape = (-3,-2), output shape = (6,4) - “-4” split
one dimension of the input into two dimensions passed subsequent to -4 in
shape (can contain -1). Example:: - input shape = (2,3,4), shape =
(4,1,2,-2), output shape = (1,2,3,4) - input shape = (2,3,4), shape =
(12,1,3,4), output shape = (2,1,3,4) If the argument ‘reverse’ is set
to 1, then the special values are inferred from right to left. Example::
- without reverse=1, for input shape = (10,5,4), shape = (-1,0), output
shape would be (40,5) - with reverse=1, output shape will be (50,4).

Defined in src/operator/tensor/matrix_op.cc:L175
**mx.nd.reshape.like**  
_Reshape some or all dimensions of ‘lhs’ to have the same shape as some or all dimensions of ‘rhs’._

### Description

Returns a **view** of the ‘lhs’ array with a new shape without altering any data.

### Arguments

- **lhs**: NDArray-or-Symbol First input.
- **rhs**: NDArray-or-Symbol Second input.
- **lhs.begin**: int or None, optional, default=’None’ Defaults to 0. The beginning index along which the lhs dimensions are to be reshaped. Supports negative indices.
- **lhs.end**: int or None, optional, default=’None’ Defaults to None. The ending index along which the lhs dimensions are to be used for reshaping. Supports negative indices.
- **rhs.begin**: int or None, optional, default=’None’ Defaults to 0. The beginning index along which the rhs dimensions are to be used for reshaping. Supports negative indices.
- **rhs.end**: int or None, optional, default=’None’ Defaults to None. The ending index along which the rhs dimensions are to be used for reshaping. Supports negative indices.
Details

Example::

x = [1, 2, 3, 4, 5, 6] y = [[0, -4], [3, 2], [2, 2]]
reshape_like(x, y) = [[1, 2], [3, 4], [5, 6]]

More precise control over how dimensions are inherited is achieved by specifying \ slices over the ‘lhs’ and ‘rhs’ array dimensions. Only the sliced ‘lhs’ dimensions \ are reshaped to the ‘rhs’ sliced dimensions, with the non-sliced ‘lhs’ dimensions staying the same.

Examples::

- lhs shape = (30,7), rhs shape = (15,2,4), lhs_begin=0, lhs_end=1, rhs_begin=0, rhs_end=2, output shape = (15,2,7) - lhs shape = (3, 5), rhs shape = (1,15,4), lhs_begin=0, lhs_end=2, rhs_begin=1, rhs_end=2, output shape = (15)

Negative indices are supported, and ‘None‘ can be used for either ‘lhs_end‘ or ‘rhs_end‘ to indicate the end of the range.

Example::

- lhs shape = (30, 12), rhs shape = (4, 2, 2, 3), lhs_begin=-1, lhs_end=None, rhs_begin=1, rhs_end=None, output shape = (30, 2, 2, 3)

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L511

Value

out The result mx.ndarray

mx.nd.reverse

Reverses the order of elements along given axis while preserving array shape. Note: reverse and flip are equivalent. We use reverse in the following examples. Examples::

x = [[0., 1., 2., 3., 4.], [5., 6., 7., 8., 9.]]
reverse(x, axis=0) = [[5., 6., 7., 8., 9.], [0., 1., 2., 3., 4.]]
reverse(x, axis=1) = [[4., 3., 2., 1., 0.], [9., 8., 7., 6., 5.]]

Defined in src/operator/tensor/matrix_op.cc:L832

Arguments

data NDArray-or-Symbol Input data array
axis Shape(tuple), required The axis which to reverse elements.

Value

out The result mx.ndarray
mx.nd.rint  
Returns element-wise rounded value to the nearest integer of the input.

Description

.. note:: - For input “n.5“ “rint“ returns “n” while “round“ returns “n+1“. - For input “-n.5“ both “rint“ and “round“ returns “-n-1“.

Arguments

data NDArray-or-Symbol The input array.

Details

Example::

rint([-1.5, 1.5, -1.9, 1.9, 2.1]) = [-2., 1., -2., 2., 2.]

The storage type of “rint“ output depends upon the input storage type:

- rint(default) = default  - rint(row_sparse) = row_sparse  - rint(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L798

Value

out The result mx.ndarray

mx.nd.rmsprop.update  Update function for ‘RMSProp’ optimizer.

Description

‘RMSprop’ is a variant of stochastic gradient descent where the gradients are divided by a cache which grows with the sum of squares of recent gradients?

Arguments

weight NDArray-or-Symbol Weight
grad NDArray-or-Symbol Gradient
n NDArray-or-Symbol n
lr float, required Learning rate
gamma float, optional, default=0.949999988 The decay rate of momentum estimates.
epsilon float, optional, default=9.99999994e-09 A small constant for numerical stability.
wd float, optional, default=0 Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
rescale.grad  float, optional, default=1  Rescale gradient to grad = rescale_grad*grad.
clip.gradient  float, optional, default=-1  Clip gradient to the range of [-clip_gradient, clip_gradient]
If clip_gradient <= 0, gradient clipping is turned off.  grad = max(min(grad, clip_gradient), -clip_gradient).
clip.weights  float, optional, default=-1  Clip weights to the range of [-clip_weights, clip_weights]
If clip_weights <= 0, weight clipping is turned off.  weights = max(min(weights, clip_weights), -clip_weights).

Details

‘RMSProp’ is similar to ‘AdaGrad’, a popular variant of ‘SGD’ which adaptively tunes the learning rate of each parameter. ‘AdaGrad’ lowers the learning rate for each parameter monotonically over the course of training. While this is analytically motivated for convex optimizations, it may not be ideal for non-convex problems. ‘RMSProp’ deals with this heuristically by allowing the learning rates to rebound as the denominator decays over time.

Define the Root Mean Square (RMS) error criterion of the gradient as \( \text{RMS}[g]_t = \sqrt{E[g^2]_t + \epsilon} \), where \( g \) represents gradient and \( E[g^2]_t \) is the decaying average over past squared gradient.

The \( E[g^2]_t \) is given by:

\[
E[g^2]_t = \gamma * E[g^2]_{t-1} + (1-\gamma) * g_t^2
\]

The update step is

\[
\theta_{t+1} = \theta_t - \frac{\eta}{\text{RMS}[g]_t} g_t
\]

Hinton suggests the momentum term \( \gamma \) to be 0.9 and the learning rate \( \eta \) to be 0.001.

Defined in src/operator/optimizer_op.cc:L797

Value

out  The result mx.ndarray
Arguments

- **weight**: NDArray-or-Symbol Weight
- **grad**: NDArray-or-Symbol Gradient
- **n**: NDArray-or-Symbol n
- **g**: NDArray-or-Symbol g
- **delta**: NDArray-or-Symbol delta
- **lr**: float, required Learning rate
- **gamma1**: float, optional, default=0.949999988 Decay rate.
- **gamma2**: float, optional, default=0.899999976 Decay rate.
- **epsilon**: float, optional, default=9.99999994e-09 A small constant for numerical stability.
- **wd**: float, optional, default=0 Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
- **rescale.grad**: float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
- **clip.gradient**: float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient] If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).
- **clip.weights**: float, optional, default=-1 Clip weights to the range of [-clip_weights, clip_weights] If clip_weights <= 0, weight clipping is turned off. weights = max(min(weights, clip_weights), -clip_weights).

Details

Define $E[g^2]_t$ is the decaying average over past squared gradient and $E[g]_t$ is the decaying average over past gradient.

\[
E[g^2]_t = \gamma_1 * E[g^2]_{t-1} + (1 - \gamma_1) * g_t^2 \\
E[g]_t = \gamma_1 * E[g]_{t-1} + (1 - \gamma_1) * g_t \\
\Delta_t = \gamma_2 * \Delta_{t-1} - \frac{\eta}{\sqrt{E[g^2]_t - E[g]_t^2 + \epsilon}} g_t
\]

The update step is

\[
\theta_{t+1} = \theta_t + \Delta_t
\]

The RMSPropAlex code follows the version in http://arxiv.org/pdf/1308.0850v5.pdf Eq(38) - Eq(45) by Alex Graves, 2013.

Graves suggests the momentum term $\gamma_1$ to be 0.95, $\gamma_2$ to be 0.9 and the learning rate $\eta$ to be 0.0001.

Defined in src/operator/optimizer_op.cc:L836

Value

- **out**: The result mx.nd.ndarray
Applies recurrent layers to input data. Currently, vanilla RNN, LSTM and GRU are implemented, with both multi-layer and bidirectional support.

Description

When the input data is of type float32 and the environment variables MXNET_CUDA_ALLOW_TENSOR_CORE and MXNET_CUDA_TENSOR_OP_MATH_ALLOW_CONVERSION are set to 1, this operator will try to use pseudo-float16 precision (float32 math with float16 I/O) precision in order to use Tensor Cores on suitable NVIDIA GPUs. This can sometimes give significant speedups.

Arguments

data NDArray-or-Symbol Input data to RNN
parameters NDArray-or-Symbol Vector of all RNN trainable parameters concatenated
state NDArray-or-Symbol initial hidden state of the RNN
state.cell NDArray-or-Symbol initial cell state for LSTM networks (only for LSTM)
sequence.length NDArray-or-Symbol Vector of valid sequence lengths for each element in batch. (Only used if use_sequence_length kwarg is True)
state.size int (non-negative), required size of the state for each layer
num.layers int (non-negative), required number of stacked layers
bidirectional boolean, optional, default=0 whether to use bidirectional recurrent layers
mode ‘gru’, ‘lstm’, ‘rnn_relu’, ‘rnn_tanh’, required the type of RNN to compute
p float, optional, default=0 drop rate of the dropout on the outputs of each RNN layer, except the last layer.
state.outputs boolean, optional, default=0 Whether to have the states as symbol outputs.
projection.size int or None, optional, default=’None’ size of project size
lstm.state.clip.min double or None, optional, default=None Minimum clip value of LSTM states. This option must be used together with lstm.state.clip_max.
lstm.state.clip.max double or None, optional, default=None Maximum clip value of LSTM states. This option must be used together with lstm.state.clip_min.
lstm.state.clip.nan boolean, optional, default=0 Whether to stop NaN from propagating in state by clipping it to min/max. If clipping range is not specified, this option is ignored.
use.sequence.length boolean, optional, default=0 If set to true, this layer takes in an extra input parameter ‘sequence_length’ to specify variable length sequence
Details

**Vanilla RNN**
Applies a single-gate recurrent layer to input X. Two kinds of activation function are supported: ReLU and Tanh.

With ReLU activation function:

.. math:: h_t = \text{relu}(W_{ih} * x_t + b_{ih} + W_{hh} * h_{(t-1)} + b_{hh})

With Tanh activation function:

.. math:: h_t = \tanh(W_{ih} * x_t + b_{ih} + W_{hh} * h_{(t-1)} + b_{hh})

**LSTM**

.. math:: \begin{array}{ll} i_t = \text{mathrsigmoid}(W_{ii} x_t + b_{ii} + W_{hi} h_{(t-1)} + b_{hi}) \ y_t = \text{mathrsigmoid}(W_{if} x_t + b_{if} + W_{hf} h_{(t-1)} + b_{hf}) \ g_t = \tanh(W_{ig} x_t + b_{ig} + W_{hc} h_{(t-1)} + b_{hg}) \ o_t = \text{mathrsigmoid}(W_{io} x_t + b_{io} + W_{ho} h_{(t-1)} + b_{ho}) \ c_t = f_t * c_{(t-1)} + i_t * g_t \ h_t = o_t * \tanh(c_t) \ y_t = W_{hr} h_t \end{array}

With the projection size being set, LSTM could use the projection feature to reduce the parameters size and give some speedups without significant damage to the accuracy.

.. math:: \begin{array}{ll} i_t = \text{mathrsigmoid}(W_{ii} x_t + b_{ii} + W_{ri} r_{(t-1)} + b_{ri}) \ y_t = \text{mathrsigmoid}(W_{if} x_t + b_{if} + W_{rf} r_{(t-1)} + b_{rf}) \ g_t = \tanh(W_{ig} x_t + b_{ig} + W_{rc} r_{(t-1)} + b_{rg}) \ o_t = \text{mathrsigmoid}(W_{io} x_t + b_{o} + W_{ro} r_{(t-1)} + b_{ro}) \ c_t = f_t * c_{(t-1)} + i_t * g_t \ h_t = o_t * \tanh(c_t) \ r_t = W_{hr} h_t \end{array}

**GRU**

The definition of GRU here is slightly different from paper but compatible with CUDNN.

.. math:: \begin{array}{ll} r_t = \text{mathrsigmoid}(W_{ir} x_t + b_{ir} + W_{hr} h_{(t-1)} + b_{hr}) \ z_t = \text{mathrsigmoid}(W_{iz} x_t + b_{iz} + W_{hz} h_{(t-1)} + b_{hz}) \ n_t = \tanh(W_{in} x_t + b_{in} + r_t * (W_{hn} h_{(t-1)} + b_{hn})) \ h_t = (1 - z_t) * n_t + z_t * h_{(t-1)} \end{array}

Defined in src/operator/rnn.cc:L369

Value

out The result mx.ndarray
mx.nd.ROI Pooling

Perform region of interest (ROI) pooling on the input array.

Description

ROI pooling is a variant of a max pooling layer, in which the output size is fixed and region of interest is a parameter. Its purpose is to perform max pooling on the inputs of non-uniform sizes to obtain fixed-size feature maps. ROI pooling is a neural-net layer mostly used in training a ‘Fast R-CNN’ network for object detection.

Arguments

data NDArray-or-Symbol The input array to the pooling operator, a 4D Feature maps
rois NDArray-or-Symbol Bounding box coordinates, a 2D array of [[batch_index, x1, y1, x2, y2]], where (x1, y1) and (x2, y2) are top left and bottom right corners of designated region of interest. ‘batch_index’ indicates the index of corresponding image in the input array
pooled.size Shape(tuple), required ROI pooling output shape (h,w)
spatial.scale float, required Ratio of input feature map height (or w) to raw image height (or w). Equals the reciprocal of total stride in convolutional layers

Details

This operator takes a 4D feature map as an input array and region proposals as ‘rois’, then it pools over sub-regions of input and produces a fixed-sized output array regardless of the ROI size.
To crop the feature map accordingly, you can resize the bounding box coordinates by changing the parameters ‘rois’ and ‘spatial_scale’.
The cropped feature maps are pooled by standard max pooling operation to a fixed size output indicated by a ‘pooled_size’ parameter. batch_size will change to the number of region bounding boxes after ‘ROI Pooling’.
The size of each region of interest doesn’t have to be perfectly divisible by the number of pooling sections(‘pooled_size’).

Example:

```python
// region of interest i.e. bounding box coordinates. y = [[0,0,0,4,4]]
// returns array of shape (2,2) according to the given roi with max pooling. ROI Pooling(x, y, (2,2), 1.0) = [[[ 14., 16.], [ 26., 28.]]]
// region of interest is changed due to the change in ‘spacial_scale’ parameter. ROI Pooling(x, y, (2,2), 0.7) = [[[ 7., 9.], [ 19., 21.]]]
```

Defined in src/operator/roi_pooling.cc:L225
Value

out The result mx.nd.array

mx.nd.round

Returns element-wise rounded value to the nearest integer of the input.

Description

Example::

Arguments

data NDArray-or-Symbol The input array.

Details

round([-1.5, 1.5, -1.9, 1.9, 2.1]) = [-2., 2., -2., 2., 2.]

The storage type of “round” output depends upon the input storage type:
- round(default) = default - round(row_sparse) = row_sparse - round(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L777

Value

out The result mx.nd.array

mx.nd.rsqrt

Returns element-wise inverse square-root value of the input.

Description

\[ rsqrt(x) = \frac{1}{\sqrt{x}} \]

Arguments

data NDArray-or-Symbol The input array.

Details

rsqrt([4,9,16]) = [0.5, 0.33333334, 0.25]

The storage type of “rsqrt” output is always dense

Defined in src/operator/tensor/elemwise_unary_op_pow.cc:L221

Value

out The result mx.nd.array
mx.nd.sample.exponential

Concurrent sampling from multiple exponential distributions with parameters lambda (rate).

Description

The parameters of the distributions are provided as an input array. Let *[s]* be the shape of the input array, *n* be the dimension of *[s]*, *[t]* be the shape specified as the parameter of the operator, and *m* be the dimension of *[t]*. Then the output will be a *(n+m)*-dimensional array with shape *[s]*x*[t]*.

Arguments

- **lam**
  NDArray-or-Symbol Lambda (rate) parameters of the distributions.
- **shape**
  Shape(tuple), optional, default=[] Shape to be sampled from each random distribution.
- **dtype**
  'None', 'float16', 'float32', 'float64', optional, default='None' DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).

Details

For any valid *n*-dimensional index *i* with respect to the input array, *output[i]* will be an *m*-dimensional array that holds randomly drawn samples from the distribution which is parameterized by the input value at index *i*. If the shape parameter of the operator is not set, then one sample will be drawn per distribution and the output array has the same shape as the input array.

Examples::

```python
lam = [ 1.0, 8.5 ]
// Draw a single sample for each distribution sample_exponential(lam) = [ 0.51837951, 0.09994757 ]
// Draw a vector containing two samples for each distribution sample_exponential(lam, shape=(2)) = [[ 0.51837951, 0.19866663], [ 0.09994757, 0.50447971]]
```

Defined in src/operator/random/multisample_op.cc:L284

Value

- **out** The result mx.ndarray
mx.nd.sample.gamma  

Concurrent sampling from multiple gamma distributions with parameters *alpha* (shape) and *beta* (scale).

**Description**

The parameters of the distributions are provided as input arrays. Let *s* be the shape of the input arrays, *n* be the dimension of *s*, *t* be the shape specified as the parameter of the operator, and *m* be the dimension of *t*. Then the output will be a *(n+m)*-dimensional array with shape *s|x|t*.

**Arguments**

- **alpha**: NDArray-or-Symbol Alpha (shape) parameters of the distributions.
- **shape**: Shape(tuple), optional, default=[] Shape to be sampled from each random distribution.
- **dtype**: 'None', 'float16', 'float32', 'float64', optional, default='None' DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).
- **beta**: NDArray-or-Symbol Beta (scale) parameters of the distributions.

**Details**

For any valid *n*-dimensional index *i* with respect to the input arrays, *output[i]* will be an *m*-dimensional array that holds randomly drawn samples from the distribution which is parameterized by the input values at index *i*. If the shape parameter of the operator is not set, then one sample will be drawn per distribution and the output array has the same shape as the input arrays.

Examples:

```python
alpha = [ 0.0, 2.5 ] beta = [ 1.0, 0.7 ]
// Draw a single sample for each distribution
sample_gamma(alpha, beta) = [ 0. , 2.25797319]
// Draw a vector containing two samples for each distribution
sample_gamma(alpha, beta, shape=(2))
= [[ 0. , 0. ], [ 2.25797319, 1.70734084]]
```

Defined in src/operator/random/multisample_op.cc:L282

**Value**

out The result mx.ndarray
Concurrent sampling from multiple generalized negative binomial distributions with parameters *mu* (mean) and *alpha* (dispersion).

**Description**

The parameters of the distributions are provided as input arrays. Let *s* be the shape of the input arrays, *n* be the dimension of *s*, *t* be the shape specified as the parameter of the operator, and *m* be the dimension of *t*. Then the output will be an *(n+m)*-dimensional array with shape *s*t.

**Arguments**

- **mu**: NDArray-or-Symbol Means of the distributions.
- **shape**: Shape(tuple), optional, default=[] Shape to be sampled from each random distribution.
- **dtype**: None, float16, float32, float64, optional, default=None DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).
- **alpha**: NDArray-or-Symbol Alpha (dispersion) parameters of the distributions.

**Details**

For any valid *n*-dimensional index *i* with respect to the input arrays, *output[i]* will be an *m*-dimensional array that holds randomly drawn samples from the distribution which is parameterized by the input values at index *i*. If the shape parameter of the operator is not set, then one sample will be drawn per distribution and the output array has the same shape as the input arrays.

Samples will always be returned as a floating point data type.

Examples:

```
mu = [ 2.0, 2.5 ] alpha = [ 1.0, 0.1 ]
// Draw a single sample for each distribution sample_generalized_negative_binomial(mu, alpha) = [ 0., 3.]
// Draw a vector containing two samples for each distribution sample_generalized_negative_binomial(mu, alpha, shape=(2)) = [[ 0., 3.], [ 3., 1.]]
```

Defined in src/operator/random/multisample_op.cc:L293

**Value**

```
out The result mx.ndarray
```

mx.nd.sample.multinomial

Concurrent sampling from multiple multinomial distributions.

Description
*data* is an *n* dimensional array whose last dimension has length *k*, where *k* is the number of possible outcomes of each multinomial distribution. This operator will draw *shape* samples from each distribution. If shape is empty one sample will be drawn from each distribution.

Arguments
- **data**: NDArray-or-Symbol Distribution probabilities. Must sum to one on the last axis.
- **shape**: Shape(tuple), optional, default=[] Shape to be sampled from each random distribution.
- **get_prob**: boolean, optional, default=0 Whether to also return the log probability of sampled result. This is usually used for differentiating through stochastic variables, e.g. in reinforcement learning.
- **dtype**: ‘float16’, ‘float32’, ‘float64’, ‘int32’, ‘uint8’.optional, default=’int32’ DType of the output in case this can’t be inferred.

Details
If *get_prob* is true, a second array containing log likelihood of the drawn samples will also be returned. This is usually used for reinforcement learning where you can provide reward as head gradient for this array to estimate gradient.

Note that the input distribution must be normalized, i.e. *data* must sum to 1 along its last axis.

Examples::
probs = [[0, 0.1, 0.2, 0.3, 0.4], [0.4, 0.3, 0.2, 0.1, 0]]
// Draw a single sample for each distribution sample_multinomial(probs) = [3, 0]
// Draw a vector containing two samples for each distribution sample_multinomial(probs, shape=(2))
= [[4, 2], [0, 0]]
// requests log likelihood sample_multinomial(probs, get_prob=True) = [2, 1], [0.2, 0.3]

Value
out The result mx.nd.array
mx.nd.sample.negative.binomial

Concurrent sampling from multiple negative binomial distributions with parameters *k* (failure limit) and *p* (failure probability).

**Description**

The parameters of the distributions are provided as input arrays. Let *s* be the shape of the input arrays, *n* be the dimension of *s*, *t* be the shape specified as the parameter of the operator, and *m* be the dimension of *t*. Then the output will be an *(n+m)*-dimensional array with shape *s x t*.

**Arguments**

- **k**
  NDArray-or-Symbol Limits of unsuccessful experiments.
- **shape**
  Shape(tuple), optional, default=[] Shape to be sampled from each random distribution.
- **dtype**
  'None', 'float16', 'float32', 'float64', optional, default='None' DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).
- **p**
  NDArray-or-Symbol Failure probabilities in each experiment.

**Details**

For any valid *n* dimensional index *i* with respect to the input arrays, *output[i]* will be an *m* dimensional array that holds randomly drawn samples from the distribution which is parameterized by the input values at index *i*. If the shape parameter of the operator is not set, then one sample will be drawn per distribution and the output array has the same shape as the input arrays.

Samples will always be returned as a floating point data type.

**Examples**:

```python
k = [ 20, 49 ] p = [ 0.4 , 0.77 ]

// Draw a single sample for each distribution
sample_negative_binomial(k, p) = [ 15., 16.]

// Draw a vector containing two samples for each distribution
sample_negative_binomial(k, p, shape=(2)) = [[ 15., 50.], [ 16., 12.]]
```

Defined in src/operator/random/multisample_op.cc:L289

**Value**

- **out** The result mx.nd.array
mx.nd.sample.normal  
Concurrent sampling from multiple normal distributions with parameters *mu* (mean) and *sigma* (standard deviation).

**Description**

The parameters of the distributions are provided as input arrays. Let *[s]* be the shape of the input arrays, *n* be the dimension of *[s]*, *[t]* be the shape specified as the parameter of the operator, and *m* be the dimension of *[t]*. Then the output will be a *(n+m)*-dimensional array with shape *[s]*x*[t]*.

**Arguments**

- **mu**: NDArray-or-Symbol Means of the distributions.
- **shape**: Shape(tuple), optional, default=[] Shape to be sampled from each random distribution.
- **dtype**: 'None', 'float16', 'float32', 'float64', optional, default='None' DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).
- **sigma**: NDArray-or-Symbol Standard deviations of the distributions.

**Details**

For any valid *n*-dimensional index *i* with respect to the input arrays, *output[i]* will be an *m*-dimensional array that holds randomly drawn samples from the distribution which is parameterized by the input values at index *i*. If the shape parameter of the operator is not set, then one sample will be drawn per distribution and the output array has the same shape as the input arrays.

**Examples**:

```python
mu = [ 0.0, 2.5 ]
sigma = [ 1.0, 3.7 ]

// Draw a single sample for each distribution
sample_normal(mu, sigma) = [-0.56410581, 0.95934606]

// Draw a vector containing two samples for each distribution
sample_normal(mu, sigma, shape=(2)) = [[-0.56410581, 0.2928229 ], [ 0.95934606, 4.48287058]]
```

Defined in src/operator/random/multisample_op.cc:L279

**Value**

- **out**: The result mx.nd.array
mx.nd.sample.poisson

Concurrent sampling from multiple Poisson distributions with parameters lambda (rate).

Description

The parameters of the distributions are provided as an input array. Let \([s]\) be the shape of the input array, \(n\) be the dimension of \([s]\), \([t]\) be the shape specified as the parameter of the operator, and \(m\) be the dimension of \([t]\). Then the output will be a \((n+m)\)-dimensional array with shape \([s]x[t]\).

Arguments

- lam: NDArray-or-Symbol Lambda (rate) parameters of the distributions.
- shape: Shape(tuple), optional, default=[] Shape to be sampled from each random distribution.
- dtype: 'None', 'float16', 'float32', 'float64', optional, default='None' DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).

Details

For any valid \(n\)-dimensional index \(i\) with respect to the input array, \(output[i]\) will be an \(m\)-dimensional array that holds randomly drawn samples from the distribution which is parameterized by the input value at index \(i\). If the shape parameter of the operator is not set, then one sample will be drawn per distribution and the output array has the same shape as the input array.

Samples will always be returned as a floating point data type.

Examples::

```python
lam = [ 1.0, 8.5 ]
// Draw a single sample for each distribution sample_poisson(lam) = [ 0., 13.]
// Draw a vector containing two samples for each distribution sample_poisson(lam, shape=(2)) = [[ 0., 4.], [ 13., 8.]]
```

Defined in src/operator/random/multisample_op.cc:L286

Value

out The result mx.ndarray
mx.nd.sample.uniform

Concurrent sampling from multiple uniform distributions on the intervals given by *[low,high]*.

Description

The parameters of the distributions are provided as input arrays. Let *[s]* be the shape of the input arrays, *[n]* be the dimension of *[s]*, *[t]* be the shape specified as the parameter of the operator, and *[m]* be the dimension of *[t]*. Then the output will be a *(n+m)*-dimensional array with shape *[s]x[t]*.

Arguments

- **low**
  NDArray-or-Symbol Lower bounds of the distributions.
- **shape**
  Shape(tuple), optional, default=[] Shape to be sampled from each random distribution.
- **dtype**
  'None', 'float16', 'float32', 'float64', optional, default='None' DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).
- **high**
  NDArray-or-Symbol Upper bounds of the distributions.

Details

For any valid *[n]*-dimensional index *[i]* with respect to the input arrays, *[output][i]* will be an *[m]*-dimensional array that holds randomly drawn samples from the distribution which is parameterized by the input values at index *[i]*. If the shape parameter of the operator is not set, then one sample will be drawn per distribution and the output array has the same shape as the input arrays.

Examples:

- low = [ 0.0, 2.5 ] high = [ 1.0, 3.7 ]

  // Draw a single sample for each distribution
  sample_uniform(low, high) = [ 0.40451524, 3.18687344]

  // Draw a vector containing two samples for each distribution
  sample_uniform(low, high, shape=(2))
  = [[ 0.40451524, 0.18017688], [ 3.18687344, 3.68352246]]

Defined in src/operator/random/multisample_op.cc:L277

Value

- **out** The result mx.ndarray
mx.nd.save

Save an mx.nd.array object

Description

Save an mx.nd.array object

Usage

mx.nd.save(ndarray, filename)

Arguments

ndarray: the mx.nd.array object
filename: the filename (including the path)

Examples

mat = mx.nd.array(1:3)
mx.nd.save(mat, 'temp.mat')
mat2 = mx.nd.load('temp.mat')
as.array(mat)
as.array(mat2[[1]])

mx.nd.scatter.nd

Scatters data into a new tensor according to indices.

Description

Given ‘data’ with shape ‘(Y_0, ..., Y_K-1, X_M, ..., X_N-1)’ and indices with shape ‘(M, Y_0, ..., Y_K-1)’, the output will have shape ‘(X_0, X_1, ..., X_N-1)’, where ‘M <= N’. If ‘M == N’, data shape should simply be ‘(Y_0, ..., Y_K-1)’.

Arguments

data: NDArray-or-Symbol data
indices: NDArray-or-Symbol indices
shape: Shape(tuple), required Shape of output.
Details

The elements in output is defined as follows:

\[
\text{output}[\text{indices}[0, y_0, ..., y_{K-1}], ..., \text{indices}[M-1, y_0, ..., y_{K-1}], x_M, ..., x_{N-1}] = \text{data}[y_0, ..., y_{K-1}, x_M, ..., x_{N-1}]
\]

all other entries in output are 0.

.. warning::

If the indices have duplicates, the result will be non-deterministic and the gradient of 'scatter_nd' will not be correct!!

Examples::

data = [2, 3, 0] indices = [[1, 1, 0], [0, 1, 0]] shape = (2, 2) scatter_nd(data, indices, shape) = [[0, 0], [2, 3]]

data = [[[1, 2], [3, 4]], [[5, 6], [7, 8]]] indices = [[0, 1], [1, 1]] shape = (2, 2, 2) scatter_nd(data, indices, shape) = [[[0, 0], [0, 0]],
[[1, 2], [3, 4]]],
[[0, 0], [0, 0]],
[[5, 6], [7, 8]]]

Value

out The result mx.ndarray

mx.nd.SequenceLast

Takes the last element of a sequence.

Description

This function takes an n-dimensional input array of the form [max_sequence_length, batch_size, other_feature_dims] and returns a (n-1)-dimensional array of the form [batch_size, other_feature_dims].

Arguments

data NDArray-or-Symbol n-dimensional input array of the form [max_sequence_length, batch_size, other_feature_dims] where n>2

sequence.length NDArray-or-Symbol vector of sequence lengths of the form [batch_size]

use.sequence.length boolean, optional, default=0 If set to true, this layer takes in an extra input parameter ‘sequence_length’ to specify variable length sequence

axis int, optional, default=’0’ The sequence axis. Only values of 0 and 1 are currently supported.
**Details**

Parameter `sequence_length` is used to handle variable-length sequences. 'sequence_length' should be an input array of positive ints of dimension [batch_size]. To use this parameter, set `use_sequence_length` to 'True', otherwise each example in the batch is assumed to have the max sequence length.

.. note:: Alternatively, you can also use 'take' operator.

Example::

```python
x = [[[ 1., 2., 3.], [ 4., 5., 6.], [ 7., 8., 9.]],

// returns last sequence when sequence_length parameter is not used
SequenceLast(x) = [[[ 19., 20., 21.], [ 22., 23., 24.], [ 25., 26., 27.]]]

// sequence_length is used
SequenceLast(x, sequence_length=[1,1,1], use_sequence_length=True) =
[[ [ 1., 2., 3.], [ 4., 5., 6.], [ 7., 8., 9.]],
```

Defined in `src/operator/sequence_last.cc:L106`

**Value**

out The result mx.ndarray

-------

**mx.nd.SequenceMask**

Sets all elements outside the sequence to a constant value.

**Description**

This function takes an n-dimensional input array of the form [max_sequence_length, batch_size, other_feature_dims] and returns an array of the same shape.

**Arguments**

- `data` NDArray-or-Symbol n-dimensional input array of the form [max_sequence_length, batch_size, other_feature_dims] where n>2
- `sequence.length` NDArray-or-Symbol vector of sequence lengths of the form [batch_size]
- `use.sequence.length` boolean, optional, default=0 If set to true, this layer takes in an extra input parameter 'sequence_length' to specify variable length sequence
- `value` float, optional, default=0 The value to be used as a mask.
- `axis` int, optional, default='0' The sequence axis. Only values of 0 and 1 are currently supported.
mx.nd.SequenceReverse

Details

Parameter 'sequence_length' is used to handle variable-length sequences. 'sequence_length' should be an input array of positive ints of dimension [batch_size]. To use this parameter, set 'use_sequence_length' to 'True', otherwise each example in the batch is assumed to have the max sequence length and this operator works as the 'identity' operator.

Example::

```python
x = [[[ 1., 2., 3.], [ 4., 5., 6.]],
     [[ 7., 8., 9.], [10., 11., 12.]],
     [[13., 14., 15.], [16., 17., 18.]]]

// Batch 1 B1 = [[[ 1., 2., 3.], [ 7., 8., 9.], [13., 14., 15.]]

// works as identity operator when sequence_length parameter is not used
SequenceMask(x) = [[[ 1., 2., 3.], [ 4., 5., 6.]],
                    [[ 7., 8., 9.], [10., 11., 12.]],
                    [[13., 14., 15.], [16., 17., 18.]]]

// sequence_length [1,1] means 1 of each batch will be kept // and other rows are masked with
default mask value = 0
SequenceMask(x, sequence_length=[1,1], use_sequence_length=True) = [[[ 1., 2., 3.], [ 4., 5., 6.]],
                                                                        [[ 0., 0., 0.], [ 0., 0., 0.]],
                                                                        [[ 0., 0., 0.], [ 0., 0., 0.]]]

// sequence_length [2,3] means 2 of batch B1 and 3 of batch B2 will be kept // and other rows
are masked with value = 1
SequenceMask(x, sequence_length=[2,3], use_sequence_length=True, value=1) = [[[ 1., 2., 3.], [ 4., 5., 6.]],
                                                                          [[ 7., 8., 9.], [10., 11., 12.]],
                                                                          [[ 1., 1., 1.], [16., 17., 18.]]]

Defined in src/operator/sequence_mask.cc:L186
```

Value

```python
out The result mx.ndarray
```

mx.nd.SequenceReverse  Reverses the elements of each sequence.

Description

This function takes an n-dimensional input array of the form [max_sequence_length, batch_size, other_feature_dims] and returns an array of the same shape.
mx.nd.SequenceReverse

Arguments

data: NDArray-or-Symbol n-dimensional input array of the form [max_sequence_length, batch_size, otherdims] where n>2

sequence_length: NDArray-or-Symbol vector of sequence lengths of the form [batch_size]

use_sequence_length: boolean, optional, default=0 If set to true, this layer takes in an extra input parameter 'sequence_length' to specify variable length sequence

axis: int, optional, default=’0’ The sequence axis. Only 0 is currently supported.

Details

Parameter 'sequence_length' is used to handle variable-length sequences. 'sequence_length' should be an input array of positive ints of dimension [batch_size]. To use this parameter, set 'use_sequence_length' to 'True', otherwise each example in the batch is assumed to have the max sequence length.

Example::

x = [[1., 2., 3.], [4., 5., 6.]],
[[7., 8., 9.], [10., 11., 12.]],
[[13., 14., 15.], [16., 17., 18.]]]
// Batch 1 B1 = [[1., 2., 3.], [7., 8., 9.], [13., 14., 15.]]
// returns reverse sequence when sequence_length parameter is not used SequenceReverse(x) = [[[13., 14., 15.], [16., 17., 18.]]],
[[7., 8., 9.], [10., 11., 12.]],
[[1., 2., 3.], [4., 5., 6.]]
// sequence_length [2,2] means 2 rows of // both batch B1 and B2 will be reversed. SequenceReverse(x, sequence_length=[2,2], use_sequence_length=True) = [[[7., 8., 9.], [10., 11., 12.]],
[[1., 2., 3.], [4., 5., 6.]],
[[13., 14., 15.], [16., 17., 18.]]]
// sequence_length [2,3] means 2 of batch B2 and 3 of batch B3 // will be reversed. SequenceReverse(x, sequence_length=[2,3], use_sequence_length=True) = [[[7., 8., 9.], [16., 17., 18.]],
[[1., 2., 3.], [10., 11., 12.]],
[[13., 14., 15.], [4., 5., 6.]]]
Defined in src/operator/sequence_reverse.cc:L122

Value

out The result mx.nd.array
mx.nd.sgd.mom.update  
*Momentum update function for Stochastic Gradient Descent (SGD) optimizer.*

**Description**

Momentum update has better convergence rates on neural networks. Mathematically it looks like below:

**Arguments**

- **weight**: NDArray-or-Symbol Weight
- **grad**: NDArray-or-Symbol Gradient
- **mom**: NDArray-or-Symbol Momentum
- **lr**: float, required Learning rate
- **momentum**: float, optional, default=0 The decay rate of momentum estimates at each epoch.
- **wd**: float, optional, default=0 Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
- **rescale.grad**: float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
- **clip.gradient**: float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient] If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).
- **lazy.update**: boolean, optional, default=1 If true, lazy updates are applied if gradient’s stype is row_sparse and both weight and momentum have the same stype

**Details**

.. math::

\begin{align*}
    v_1 &= \alpha \nabla J(W_0) \\
    v_t &= \gamma v_{t-1} - \alpha \nabla J(W_{t-1}) \\
    W_t &= W_{t-1} + v_t
\end{align*}

It updates the weights using:

\[ v = v - \text{learning_rate} \cdot \text{gradient} \]

Where the parameter “momentum” is the decay rate of momentum estimates at each epoch.

However, if grad’s storage type is “row_sparse”, “lazy_update” is True and weight’s storage type is the same as momentum’s storage type, only the row slices whose indices appear in grad.indices are updated (for both weight and momentum):

weight[row] += v[row]

Defined in src/operator/optimizer_op.cc:L565

**Value**

out The result mx.ndarray
mx.nd.sgd.update

Update function for Stochastic Gradient Descent (SGD) optimizer.

Description

It updates the weights using::

Arguments

weight NDArray-or-Symbol Weight
grad NDArray-or-Symbol Gradient
lr float, required Learning rate
wd float, optional, default=0 Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
rescale.grad float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
clip.gradient float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient]
    If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).
lazy.update boolean, optional, default=1 If true, lazy updates are applied if gradient’s stype is row_sparse.

Details

weight = weight - learning_rate * (gradient + wd * weight)

However, if gradient is of “row_sparse” storage type and “lazy_update“ is True, only the row slices whose indices appear in grad.indices are updated::

Defined in src/operator/optimizer_op.cc:L524

Value

out The result mx.ndarray
mx.nd.shape.array  

Returns a 1D int64 array containing the shape of data.

Description

Example::

Arguments

data  
NDArray-or-Symbol Input Array.

Details

shape_array([[1,2,3,4], [5,6,7,8]]) = [2,4]

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L573

Value

out The result mx.nd.array

mx.nd.shuffle  

Randomly shuffle the elements.

Description

This shuffles the array along the first axis. The order of the elements in each subarray does not change. For example, if a 2D array is given, the order of the rows randomly changes, but the order of the elements in each row does not change.

Arguments

data  
NDArray-or-Symbol Data to be shuffled.

Value

out The result mx.nd.array
mx.nd.sigmoid

Computes sigmoid of x element-wise.

Description

.. math:: y = 1 / (1 + \exp(-x))

Arguments

data NDArray-or-Symbol The input array.

Details

The storage type of “sigmoid” output is always dense
Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L119

Value

out The result mx.ndarray

mx.nd.sign

Returns element-wise sign of the input.

Description

Example::

Arguments

data NDArray-or-Symbol The input array.

Details

sign([-2, 0, 3]) = [-1, 0, 1]

The storage type of “sign“ output depends upon the input storage type:
- sign(default) = default - sign(row_sparse) = row_sparse - sign(csr) = csr
Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L758

Value

out The result mx.ndarray
mx.nd.signsgd.update  

Update function for SignSGD optimizer.

Description

.. math::

Arguments

- **weight**: NDArray-or-Symbol Weight
- **grad**: NDArray-or-Symbol Gradient
- **lr**: float, required Learning rate
- **wd**: float, optional, default=0 Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
- **rescale.grad**: float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
- **clip.gradient**: float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient] If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).

Details

.. math::

\text{g}_t = \nabla J(W_{t-1}) \quad W_t = W_{t-1} - \eta_t \text{sign}(g_t)

It updates the weights using::

weight = weight - learning_rate * sign(gradient)

.. note:: - sparse ndarray not supported for this optimizer yet.

Defined in src/operator/optimizer_op.cc:L63

Value

- **out**: The result mx.ndarray

mx.nd.signum.update  

SIGN momentUM (Signum) optimizer.

Description

.. math::
Arguments

weight : NDArray-or-Symbol
    Weight

grad : NDArray-or-Symbol
    Gradient

mom : NDArray-or-Symbol
    Momentum

lr : float, required
    Learning rate

momentum : float, optional, default=0
    The decay rate of momentum estimates at each epoch.

wd : float, optional, default=0
    Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.

rescale.grad : float, optional, default=1
    Rescale gradient to grad = rescale_grad*grad.

clip.gradient : float, optional, default=-1
    Clip gradient to the range of \([-\text{clip\_gradient}, \text{clip\_gradient}]\). If clip\_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip\_gradient), -clip\_gradient).

wd.lh : float, optional, default=0
    The amount of weight decay that does not go into gradient/momentum calculation otherwise do weight decay algorithmically only.

details

\[ g_t = \nabla J(W_{t-1}) \backslash \ m_t = \beta m_{t-1} + (1 - \beta) g_t \backslash W_t = W_{t-1} - \eta_t \text{sign}(m_t) \]

It updates the weights using:

\[
\text{state} = \text{momentum} \times \text{state} + (1 - \text{momentum}) \times \text{gradient} \\
\text{weight} = \text{weight} - \text{learning\_rate} \times \text{sign} (\text{state})
\]

Where the parameter “momentum” is the decay rate of momentum estimates at each epoch.

.. note:: sparse ndarray not supported for this optimizer yet.

Defined in src/operator/optimizer_op.cc:L92

Value

out The result mx.ndarray

mx.nd.sin

\text{Computes the element-wise sine of the input array.}

Description

The input should be in radians (:math:`2\pi` rad equals 360 degrees).

Arguments

data : NDArray-or-Symbol
    The input array.
Details

.. math:: \sin([0, \pi/4, \pi/2]) = [0, 0.707, 1]

The storage type of “\(\sin\)" output depends upon the input storage type:

- \(\sin\)(default) = default - \(\sin\)(row_sparse) = row_sparse - \(\sin\)(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L47

Value

out The result mx.ndarray

mx.nd.sinh

Returns the hyperbolic sine of the input array, computed element-wise.

Description

.. math:: \sinh(x) = 0.5 \times (\exp(x) - \exp(-x))

Arguments

data NDArray-or-Symbol The input array.

Details

The storage type of “\(\sinh\)" output depends upon the input storage type:

- \(\sinh\)(default) = default - \(\sinh\)(row_sparse) = row_sparse - \(\sinh\)(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L371

Value

out The result mx.ndarray

mx.nd.size.array

Returns a 1D int64 array containing the size of data.

Description

Example::

Arguments

data NDArray-or-Symbol Input Array.
mx.nd.slice.axis

Details

size_array([[1,2,3,4], [5,6,7,8]]) = [8]

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L624

Value

out The result mx.ndarray

mx.nd.slice.axis  Slices along a given axis. Returns an array slice along a given ‘axis’ starting from the ‘begin’ index to the ‘end’ index. Examples: x = [[
1., 2., 3., 4.], [ 5., 6., 7., 8.], [ 9., 10., 11., 12.]] slice_axis(x, axis=0, begin=1, end=3) = [[ 5., 6., 7., 8.], [ 9., 10., 11., 12.]] slice_axis(x, axis=1, begin=0, end=2) = [[ 1., 2.], [ 5., 6.], [ 9., 10.]] slice_axis(x, axis=1, begin=-3, end=-1) = [[ 2., 3.], [ 6., 7.], [10., 11.]]

Description

Defined in src/operator/tensor/matrix_op.cc:L571

Arguments

data NDArray-or-Symbol Source input

axis int, required Axis along which to be sliced, supports negative indexes.

begin int, required The beginning index along the axis to be sliced, supports negative indexes.

dend int or None, required The ending index along the axis to be sliced, supports negative indexes.

Value

out The result mx.ndarray
Slices a region of the array like the shape of another array. This function is similar to “slice”, however, the ‘begin’ are always ‘0’s and ‘end’ of specific axes are inferred from the second input ‘shape_like’. Given the second ‘shape_like’ input of “shape=(d_0, d_1, ..., d_n-1)”, a “slice_like” operator with default empty ‘axes’, it performs the following operation: “ out = slice(input, begin=(0, 0, ..., 0), end=(d_0, d_1, ..., d_n-1))”. When ‘axes’ is not empty, it is used to specify which axes are being sliced. Given a 4-d input data, “slice_like” operator with “axes=(0, 2, -1)” will perform the following operation: “ out = slice(input, begin=(0, 0, 0, 0), end=(d_0, None, d_2, d_3))”. Note that it is allowed to have first and second input with different dimensions, however, you have to make sure the ‘axes’ are specified and not exceeding the dimension limits. For example, given ‘input_1’ with “shape=(2,3,4,5)” and ‘input_2’ with “shape=(1,2,3)”, it is not allowed to use: “ out = slice_like(a, b)” because ndim of ‘input_1’ is 4, and ndim of ‘input_2’ is 3. The following is allowed in this situation: “ out = slice_like(a, b, axes=(0, 2))” Example:: x = [1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0, 10.0, 11.0, 12.0] y = [0.0, 0.0, 0.0, 0.0, 0.0, 0.0] slice_like(x, y) = [1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0] slice_like(x, y, axes=(0, 1)) = [1.0, 2.0, 3.0, 5.0, 6.0, 7.0] slice_like(x, y, axes=(0)) = [1.0, 2.0, 3.0, 5.0, 6.0, 7.0] slice_like(x, y, axes=(0, 1)) = [1.0, 2.0, 3.0, 5.0, 6.0, 7.0] slice_like(x, y, axes=(0, 1)) = [1.0, 2.0, 3.0, 5.0, 6.0, 7.0]

Description

Defined in src/operator/tensor/matrix_op.cc:L625

Arguments

data NDArray-or-Symbol Source input
shape_like NDArray-or-Symbol Shape like input
axes Shape(tuple), optional, default=[] List of axes on which input data will be sliced according to the corresponding size of the second input. By default will slice on all axes. Negative axes are supported.

Value

out The result mx.nd.array
mx.nd.SliceChannel

Splits an array along a particular axis into multiple sub-arrays.

Description

.. note:: “SliceChannel” is deprecated. Use “split” instead.

Arguments

- **data**: NDArray-or-Symbol The input
- **num.outputs**: int, required Number of splits. Note that this should evenly divide the length of the ‘axis’.
- **axis**: int, optional, default=`1` Axis along which to split.
- **squeeze.axis**: boolean, optional, default=`0` If true, Removes the axis with length 1 from the shapes of the output arrays. **Note** that setting ‘squeeze_axis’ to “true” removes axis with length 1 only along the ‘axis’ which it is split. Also ‘squeeze_axis’ can be set to “true” only if “input.shape[axis] == num_outputs”.

Details

**Note** that ‘num_outputs’ should evenly divide the length of the axis along which to split the array.

Example::

x = [[[ 1. ] [ 2. ]] [[ 3. ] [ 4. ]] [[ 5. ] [ 6. ]]] x.shape = (3, 2, 1)
y = split(x, axis=1, num_outputs=2) // a list of 2 arrays with shape (3, 1, 1) y = [[[ 1. ] [[ 3. ] [[ 5. ]]]
[[ 2. ]] [[ 4. ]] [[ 6. ]]]] y[0].shape = (3, 1, 1)
z = split(x, axis=0, num_outputs=3) // a list of 3 arrays with shape (1, 2, 1) z = [[[ 1. ] [ 2. ]]]
[[ 3. ] [ 4. ]]
[[ 5. ] [ 6. ]]]
z[0].shape = (1, 2, 1)

‘squeeze_axis=1’ removes the axis with length 1 from the shapes of the output arrays. **Note** that setting ‘squeeze_axis’ to “1” removes axis with length 1 only along the ‘axis’ which it is split. Also ‘squeeze_axis’ can be set to true only if “input.shape[axis] == num_outputs”.

Example::

z = split(x, axis=0, num_outputs=3, squeeze_axis=1) // a list of 3 arrays with shape (2, 1) z = [[[ 1. ] [ 2. ]]]
[[ 3. ] [ 4. ]]
[[ 5. ] [ 6. ]]] z[0].shape = (2, 1)

Defined in src/operator/slice_channel.cc:L107
mx.nd.Softmax

Description
- This operator computes the gradient in two steps. The cross entropy loss does not actually need to be computed.

mx.nd.smooth.l1

Calculate Smooth L1 Loss(lhs, scalar) by summing

Description
.. math::

Arguments
- data: NDArray-or-Symbol source input
- scalar: float scalar input

Details
\[
f(x) = \begin{cases} (\sigma x)^2/2, & \text{if } x < 1/\sigma^2 \\ |x| - 0.5/\sigma^2, & \text{otherwise} \end{cases}
\]
where :math:`x` is an element of the tensor *lhs* and :math:`\sigma` is the scalar.

Example:
smooth_l1([1, 2, 3, 4]) = [0.5, 1.5, 2.5, 3.5]
smooth_l1([1, 2, 3, 4], scalar=1) = [0.5, 1.5, 2.5, 3.5]

Defined in src/operator/tensor/elemwise_binary_scalar_op_extended.cc:L109

Value
- out: The result mx.ndarray

mx.nd.Softmax

Computes the gradient of cross entropy loss with respect to softmax output.
Arguments

- **data**: NDArray-or-Symbol Input array.
- **label**: NDArray-or-Symbol Ground truth label.
- **grad.scale**: float, optional, default=1 Scales the gradient by a float factor.
- **ignore.label**: float, optional, default=-1 The instances whose ‘labels’ == ‘ignore_label’ will be ignored during backward, if ‘use.ignore’ is set to “true”).
- **multi.output**: boolean, optional, default=0 If set to “true”, the softmax function will be computed along axis “1”. This is applied when the shape of input array differs from the shape of label array.
- **use.ignore**: boolean, optional, default=0 If set to “true”, the ‘ignore_label’ value will not contribute to the backward gradient.
- **preserve.shape**: boolean, optional, default=0 If set to “true”, the softmax function will be computed along the last axis (“-1”).
- **normalization**: 'batch', 'null', 'valid',optional, default='null' Normalizes the gradient.
- **out.grad**: boolean, optional, default=0 Multiplies gradient with output gradient element-wise.
- **smooth.alpha**: float, optional, default=0 Constant for computing a label smoothed version of cross-entropy for the backwards pass. This constant gets subtracted from the one-hot encoding of the gold label and distributed uniformly to all other labels.

Details

- Applies softmax function on the input array. - Computes and returns the gradient of cross entropy loss w.r.t. the softmax output.
- The softmax function, cross entropy loss and gradient is given by:
  - Softmax Function:
    .. math:: \textsoftmax(x)_i = \frac{\exp(x_i)}{\sum_j \exp(x_j)}
  - Cross Entropy Function:
    .. math:: \textCE(label, output) = - \sum_i \textlabel_i \log(\textoutput_i)
  - The gradient of cross entropy loss w.r.t softmax output:
    .. math:: \textgradient = \textoutput - \textlabel
  - During forward propagation, the softmax function is computed for each instance in the input array. For general *N*-D input arrays with shape :math:`(d_1, d_2, \ldots, d_n)`. The size is :math:`s=d_1 \cdot d_2 \cdot \ldots \cdot d_n`. We can use the parameters ‘preserve_shape’ and ‘multi_output’ to specify the way to compute softmax:
    - By default, ‘preserve_shape’ is “false”. This operator will reshape the input array into a 2-D array with shape :math:`(d_1, \frac{d_1}{d_2} \cdot \ldots \cdot \frac{d_1}{d_n})` and then compute the softmax function for each row in the reshaped array, and afterwards reshape it back to the original shape :math:`(d_1, d_2, \ldots, d_n)`. - If ‘preserve_shape’ is “true”, the softmax function will be computed along the last axis (‘axis’ = “-1”). - If ‘multi_output’ is “true”, the softmax function will be computed along the second axis (‘axis’ = “1”).
During backward propagation, the gradient of cross-entropy loss w.r.t softmax output array is computed. The provided label can be a one-hot label array or a probability label array.

If the parameter `use_ignore` is “true”, `ignore_label` can specify input instances with a particular label to be ignored during backward propagation. **This has no effect when softmax ‘output’ has same shape as ‘label’**.

Example:

```python
data = [[1,2,3,4],[2,2,2,2],[3,3,3,3],[4,4,4,4]]
label = [1,0,2,3]
ignore_label = 1
SoftmaxOutput(data=data, label = label, multi_output=true, use_ignore=true, ignore_label=ignore_label) # forward softmax output 
[[ 0.0320586 0.08714432 0.23688284 0.64391428] 
 [ 0.25 0.25 0.25 0.25 ] 
 [ 0.25 0.25 0.25 0.25 ]] # backward gradient output 
[[ 0. 0. 0. 0. ] 
 [-0.75 0.25 0.25 0.25] 
 [ 0.25 0.25 -0.75 0.25] 
 [ 0.25 0.25 0.25 -0.75]] # notice that the first row is all 0 because label[0] is 1, which is equal to ignore_label.
```

- The parameter ‘grad_scale’ can be used to rescale the gradient, which is often used to give each loss function different weights.

- This operator also supports various ways to normalize the gradient by ‘normalization’, The ‘normalization’ is applied if softmax output has different shape than the labels. The ‘normalization’ mode can be set to the followings:
  - ‘null’: do nothing.
  - ‘batch’: divide the gradient by the batch size.
  - ‘valid’: divide the gradient by the number of instances which are not ignored.

Defined in src/operator/softmax_output.cc:L243

Value

out The result mx.ndarray

mx.nd.softmax

Applies the softmax function.

Description

The resulting array contains elements in the range (0,1) and the elements along the given axis sum up to 1.

Arguments

data NDArray-or-Symbol The input array.

length NDArray-or-Symbol The length array.

axis int, optional, default=-1 The axis along which to compute softmax.

temperature double or None, optional, default=None Temperature parameter in softmax

dtype None, `float16`, `float32`, `float64`, optional, default=None DType of the output in case this can’t be inferred. Defaults to the same as input’s dtype if not defined (dtype=None).

use.length boolean or None, optional, default=0 Whether to use the length input as a mask over the data input.
**Details**

.. math:: \text{softmax}(\mathbf{z}/t)_j = \frac{\text{exp}(\mathbf{z}_j/t)}{\sum_k \text{exp}(\mathbf{z}_k/t)}

for :math:`j = 1, ..., K`.

`t` is the temperature parameter in softmax function. By default, `t` equals 1.0.

Example::

\[
x = [[ 1. 1. 1.] [ 1. 1. 1.]]
\]

\[
\text{softmax}(x, \text{axis}=0) = [[ 0.5 0.5 0.5] [ 0.5 0.5 0.5]]
\]

\[
\text{softmax}(x, \text{axis}=1) = [[[ 0.33333334, 0.33333334, 0.33333334], [ 0.33333334, 0.33333334, 0.33333334]]
\]

Defined in src/operator/nn/softmax.cc:L136

**Value**

out The result mx.ndarray

---

mx.nd.softmax.cross.entropy

_Calculate cross entropy of softmax output and one-hot label._

**Description**

- This operator computes the cross entropy in two steps: - Applies softmax function on the input array. - Computes and returns the cross entropy loss between the softmax output and the labels.

**Arguments**

data NDArray-or-Symbol Input data

label NDArray-or-Symbol Input label

**Details**

- The softmax function and cross entropy loss is given by:

- **Softmax Function:**

\[
\text{softmax}(x)_i = \frac{\text{exp}(x_i)}{\sum_j \text{exp}(x_j)}
\]

- **Cross Entropy Function:**

\[
\text{CE}(\text{label, output}) = - \sum_i \text{label}_i \text{log}(\text{output}_i)
\]

Example::

\[
x = [[1, 2, 3], [11, 7, 5]]
\]

\[
\text{softmax}(x) = [[0.09003057, 0.24472848, 0.66524094], [0.97962922, 0.01794253, 0.00242826]]
\]

\[
\text{softmax}_{\text{cross}}(\text{entropy}(\text{data, label}) = - \text{log}(0.66524084) - \text{log}(0.97962922) = 0.4281871
\]

Defined in src/operator/loss_binary_op.cc:L59
Value

out The result mx.ndarray

mx.nd.SoftmaxActivation

Applies softmax activation to input. This is intended for internal layers.

Description

.. note::

Arguments

data NDArray-or-Symbol The input array.

mode 'channel', 'instance', optional, default='instance' Specifies how to compute the softmax. If set to "instance", it computes softmax for each instance. If set to "channel", it computes cross channel softmax for each position of each instance.

Details

This operator has been deprecated, please use 'softmax'.

If 'mode' = "instance", this operator will compute a softmax for each instance in the batch. This is the default mode.

If 'mode' = "channel", this operator will compute a k-class softmax at each position of each instance, where 'k' = "num_channel". This mode can only be used when the input array has at least 3 dimensions. This can be used for 'fully convolutional network', 'image segmentation', etc.

Example::

    »> input_array = mx.nd.array([[3., 0.5, -0.5, 2., 7.], »> [2., -.4, 7., 3., 0.2]]) »> softmax_act = mx.nd.SoftmaxActivation(input_array) »> print softmax_act.asnumpy() »> [ 1.78322066e-02 1.46375655e-03 5.38485940e-04 6.56010211e-03 9.73605454e-01] [ 6.56221947e-03 1.78379621e-02 9.73919690e-01 1.78379621e-02 1.08472735e-03]

Defined in src/operator/nn/softmax_activation.cc:L59

Value

out The result mx.ndarray
mx.nd.SoftmaxOutput

Computes the gradient of cross entropy loss with respect to softmax output.

Description

- This operator computes the gradient in two steps. The cross entropy loss does not actually need to be computed.

Arguments

data: NDArray-or-Symbol Input array.
label: NDArray-or-Symbol Ground truth label.
gradients: float, optional, default=1 Scales the gradient by a float factor.
ignore.label: float, optional, default=-1 The instances whose 'labels' == 'ignore_label' will be ignored during backward, if 'use_ignore' is set to 'true').
multi.output: boolean, optional, default=0 If set to "true", the softmax function will be computed along axis "1". This is applied when the shape of input array differs from the shape of label array.
use.ignore: boolean, optional, default=0 If set to "true", the 'ignore_label' value will not contribute to the backward gradient.
preserve.shape: boolean, optional, default=0 If set to "true", the softmax function will be computed along the last axis ("-1").
normalization: 'batch', 'null', 'valid', optional, default='null' Normalizes the gradient.
out.grad: boolean, optional, default=0 Multiplies gradient with output gradient elementwise.
smooth.alpha: float, optional, default=0 Constant for computing a label smoothed version of cross-entropy for the backwards pass. This constant gets subtracted from the one-hot encoding of the gold label and distributed uniformly to all other labels.

Details

- Applies softmax function on the input array. - Computes and returns the gradient of cross entropy loss w.r.t. the softmax output.
- The softmax function, cross entropy loss and gradient is given by:
  - Softmax Function:
    \[
    \text{softmax}(x)_i = \frac{\exp(x_i)}{\sum_j \exp(x_j)}
    \]
  - Cross Entropy Function:
    \[
    \text{CE(label, output)} = -\sum_i \text{label}_i \log(\text{output}_i)
    \]
  - The gradient of cross entropy loss w.r.t softmax output:
    \[
    \text{gradient} = \text{output} - \text{label}
    \]
During forward propagation, the softmax function is computed for each instance in the input array. For general N-dimensional input arrays with shape \( (d_1, d_2, ..., d_n) \). The size is \( s = d_1 \cdot d_2 \cdot \cdots \cdot d_n \). We can use the parameters ‘preserve_shape’ and ‘multi_output’ to specify the way to compute softmax:

- By default, ‘preserve_shape’ is “false“. This operator will reshape the input array into a 2-D array with shape \( (d_1, \frac{d_1}{2}) \) and then compute the softmax function for each row in the reshaped array, and afterwards reshape it back to the original shape \( (d_1, d_2, ..., d_n) \).
- If ‘preserve_shape’ is “true”, the softmax function will be computed along the last axis (‘axis’ = “-1”). If ‘multi_output’ is “true”, the softmax function will be computed along the second axis (‘axis’ = “1”).

During backward propagation, the gradient of cross-entropy loss w.r.t softmax output array is computed. The provided label can be a one-hot label array or a probability label array.

- If the parameter ‘use_ignore’ is “true”, ‘ignore_label’ can specify input instances with a particular label to be ignored during backward propagation. **This has no effect when softmax ‘output’ has same shape as ‘label’**.

Example::

data = [[1,2,3,4],[2,2,2,2],[3,3,3,3],[4,4,4,4]]
label = [1,0,2,3] ignore_label = 1
SoftmaxOutput(data=data, label = label, multi_output=true, use_ignore=true, ignore_label=ignore_label) ## forward softmax
output = [[ 0.0320586 0.08714432 0.23688284 0.64391428] [ 0.25 0.25 0.25 0.25 ] [ 0.25 0.25 0.25 0.25 ] [ 0.25 0.25 -0.75 0.25]] # back conducts the gradient by the number of instances which are not ignored.

Defined in src/operator/softmax_output.cc:L243

Value

out The result mx.ndarray

mx.nd.softmin
Applies the softmin function.

Description

The resulting array contains elements in the range (0,1) and the elements along the given axis sum up to 1.
**mx.nd.softsign**

**Arguments**
- **data**: NDArray-or-Symbol The input array.
- **axis**: int, optional, default=-1 The axis along which to compute softmax.
- **temperature**: double or None, optional, default=None Temperature parameter in softmax.
- **dtype**: None, 'float16', 'float32', 'float64', optional, default=None DType of the output in case this can’t be inferred. Defaults to the same as input’s dtype if not defined (dtype=None).
- **use.length**: boolean or None, optional, default=0 Whether to use the length input as a mask over the data input.

**Details**

.. math:: softmin(\mathbfz/t)_j = \frac{\sum_{k=1}^{K} e^{-z_k}/t}{e^{-z_j}/t}

for :math:`j = 1, ..., K`.

\( t \) is the temperature parameter in softmax function. By default, \( t \) equals 1.0.

**Example**:

```python
x = [[ 1.  2.  3.]
     [ 3.  2.  1.]]
softmin(x,axis=0) = [[ 0.88079703, 0.5, 0.11920292],
                     [ 0.11920292, 0.5, 0.88079703]]
softmin(x,axis=1) = [[ 0.66524094, 0.24472848, 0.09003057],
                     [ 0.09003057, 0.24472848, 0.66524094]]
```

Defined in src/operator/nn/softmin.cc:L57

**Value**

- **out**: The result mx.ndarray

---

**mx.nd.softsign**

*Computes softsign of x element-wise.*

**Description**

.. math:: y = x / (1 + \text{abs}(x))

**Arguments**
- **data**: NDArray-or-Symbol The input array.

**Details**

The storage type of “softsign” output is always dense.

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L191

**Value**

- **out**: The result mx.ndarray
mx.nd.sort

Returns a sorted copy of an input array along the given axis.

Description

Examples:

Arguments

data NDArray-or-Symbol The input array
axis int or None, optional, default=’-1’ Axis along which to choose sort the input
tensor. If not given, the flattened array is used. Default is -1.
is.ascend boolean, optional, default=1 Whether to sort in ascending or descending order.

Details

\[ x = \begin{bmatrix} 1 & 4 \\ 3 & 1 \end{bmatrix} \]
// sorts along the last axis \[ \text{sort}(x) = \begin{bmatrix} 1. & 4. \\ 1. & 3. \end{bmatrix} \]
// flattens and then sorts \[ \text{sort}(x, \text{axis}=\text{None}) = [ 1., 1., 3., 4. ] \]
// sorts along the first axis \[ \text{sort}(x, \text{axis}=0) = [ [ 1., 1. ] , [ 3., 4. ] ] \]
// in a descend order \[ \text{sort}(x, \text{is\_ascend}=0) = [ [ 4., 1. ] , [ 3., 1. ] ] \]

Defined in src/operator/tensor/ordering_op.cc:L133

Value

out The result mx.ndarray

mx.nd.space.to.depth

Rearranges (permutes) blocks of spatial data into depth. Similar to ONNX SpaceToDepth operator:
https://github.com/onnx/onnx/blob/master/docs/Operators.md#SpaceToDepth
The output is a new tensor where the values from height and width
dimension are moved to the depth dimension. The reverse of this
operation is “depth_to_space”. .. math:: \begin{align*}
  x' &= \text{reshape}(x, [N, C, H / \text{block\_size}, \text{block\_size}, W / \text{block\_size}, \\
    \text{block\_size}]) \\
  y &= \text{reshape}(x' \text{prime} \text{prime}, [N, C * (\text{block\_size}^2), H / \\
    \text{block\_size}, W / \text{block\_size}])
\end{align*}
where :math:`x` is an input
tensor with default layout as :math:`[N, C, H, W]`: [batch, channels, 
height, width] and :math:`y` is the output tensor of layout :math:`[N, C * (\text{block\_size}^2), H / \\
\text{block\_size}, W / \text{block\_size}]`. Example::
x = [[[0, 6, 1, 7, 2, 8], [12, 18, 13, 19, 14, 20], [3, 9, 4, 10, 5, 11], [15, 
21, 16, 22, 17, 23]]]
space_to_depth(x, 2) = [[[0, 1, 2], [3, 4, 5]], 
[[6, 7, 8], [9, 10, 11]], [[12, 13, 14], [15, 16, 17]], [[18, 19, 20], [21, 
22, 23]]]
mx.nd.SpatialTransformer

Description

Defined in src/operator/tensor/matrix_op.cc:L1019

Arguments

data NDArray-or-Symbol Input ndarray
block.size int, required Blocks of [block_size, block_size] are moved

Value

out The result mx.ndarray

Applies a spatial transformer to input feature map.

Arguments

data NDArray-or-Symbol Input data to the SpatialTransformerOp.
loc NDArray-or-Symbol localisation net, the output dim should be 6 when transform_type is affine. You should initialize the weight and bias with identity transform.
target.shape Shape(tuple), optional, default=[0,0] output shape(h, w) of spatial transformer: (y, x)
transform.type 'affine', required transformation type
sampler.type 'bilinear', required sampling type
cudnn.off boolean or None, optional, default=None whether to turn cudnn off

Value

out The result mx.ndarray
mx.nd.split

*Splits an array along a particular axis into multiple sub-arrays.*

**Description**

.. note:: “SliceChannel“ is deprecated. Use “split” instead.

**Arguments**

- **data**: NDArray-or-Symbol The input
- **num_outputs**: int, required Number of splits. Note that this should evenly divide the length of the ‘axis’.
- **axis**: int, optional, default='1’ Axis along which to split.
- **squeeze.axis**: boolean, optional, default=0 If true, Removes the axis with length 1 from the shapes of the output arrays. **Note** that setting ‘squeeze_axis’ to “true” removes axis with length 1 only along the ‘axis’ which it is split. Also ‘squeeze_axis’ can be set to “true” only if “input.shape[axis] == num_outputs”.

**Details**

**Note** that ‘num_outputs’ should evenly divide the length of the axis along which to split the array.

Example::

```python
x = [[[ 1.] [ 2.]] [[ 3.] [ 4.]] [[ 5.] [ 6.]]] x.shape = (3, 2, 1)
y = split(x, axis=1, num_outputs=2) // a list of 2 arrays with shape (3, 1, 1) y = [[[ 1.] [ 3.] [ 5.]]]
[[[ 2.]] [[ 4.]] [[ 6.]]]
y[0].shape = (3, 1, 1)
z = split(x, axis=0, num_outputs=3) // a list of 3 arrays with shape (1, 2, 1) z = [[[ 1.] [ 2.]]]
[[[ 3.] [ 4.]]]
[[[ 5.] [ 6.]]]
z[0].shape = (1, 2, 1)
```

‘squeeze_axis=1’ removes the axis with length 1 from the shapes of the output arrays. **Note** that setting ‘squeeze_axis’ to “1” removes axis with length 1 only along the ‘axis’ which it is split. Also ‘squeeze_axis’ can be set to true only if “input.shape[axis] == num_outputs”.

Example::

```python
z = split(x, axis=0, num_outputs=3, squeeze_axis=1) // a list of 3 arrays with shape (2, 1) z = [[[ 1.]]
[[ 2.]]]
[[[ 3.] [ 4.]]]
[[[ 5.] [ 6.]]] z[0].shape = (2, 1)
```

Defined in src/operator/slice_channel.cc:L107
mx.nd.sqrt

Value
out The result mx.ndarray

mx.nd.sqrt
Returns element-wise square-root value of the input.

Description
.. math:: \text{sqrt}(x) = \sqrt{x}

Arguments
data NDArray-or-Symbol The input array.

Details
Example::
sqrt([4, 9, 16]) = [2, 3, 4]
The storage type of “sqrt” output depends upon the input storage type:
- sqrt(default) = default - sqrt(row_sparse) = row_sparse - sqrt(csr) = csr
Defined in src/operator/tensor/elemwise_unary_op_pow.cc:L170

Value
out The result mx.ndarray

mx.nd.square
Returns element-wise squared value of the input.

Description
.. math:: \text{square}(x) = x^2

Arguments
data NDArray-or-Symbol The input array.

Details
Example::
square([2, 3, 4]) = [4, 9, 16]
The storage type of “square” output depends upon the input storage type:
- square(default) = default - square(row_sparse) = row_sparse - square(csr) = csr
Defined in src/operator/tensor/elemwise_unary_op_pow.cc:L119
Remove single-dimensional entries from the shape of an array. Same behavior of defining the output tensor shape as numpy.squeeze for the most of cases. See the following note for exception. Examples::
data = [[[0], [1], [2]]] squeeze(data) = [0, 1, 2] squeeze(data, axis=0) = [[0], [1], [2]] squeeze(data, axis=2) = [0, 1, 2] squeeze(data, axis=(0, 2)) = [0, 1, 2] .. Note:: The output of this operator will keep at least one dimension not removed. For example, squeeze([[4]]) = [4], while in numpy.squeeze, the output will become a scalar.

**Arguments**

- **data** : NDArray-or-Symbol data to squeeze
- **axis** : Shape or None, optional, default=None Selects a subset of the single-dimensional entries in the shape. If an axis is selected with shape entry greater than one, an error is raised.

**Value**

- **out** : The result mx.ndarray

Join a sequence of arrays along a new axis. The axis parameter specifies the index of the new axis in the dimensions of the result. For example, if axis=0 it will be the first dimension and if axis=-1 it will be the last dimension. Examples::
x = [1, 2] y = [3, 4] stack(x, y) = [[1, 2], [3, 4]] stack(x, y, axis=1) = [[1, 3], [2, 4]]

**Description**

Join a sequence of arrays along a new axis. The axis parameter specifies the index of the new axis in the dimensions of the result. For example, if axis=0 it will be the first dimension and if axis=-1 it will be the last dimension. Examples::
x = [1, 2] y = [3, 4] stack(x, y) = [[1, 2], [3, 4]] stack(x, y, axis=1) = [[1, 3], [2, 4]]
mx.nd.stop.gradient

Arguments

- data: NDArray-or-Symbol[] List of arrays to stack
- axis: int, optional, default='0' The axis in the result array along which the input arrays are stacked.
- num.args: int, required Number of inputs to be stacked.

Value

- out: The result mx.ndarray

mx.nd.stop.gradient  Stops gradient computation.

Description

Stops the accumulated gradient of the inputs from flowing through this operator in the backward direction. In other words, this operator prevents the contribution of its inputs to be taken into account for computing gradients.

Arguments

- data: NDArray-or-Symbol The input array.

Details

Example::

v1 = [1, 2] v2 = [0, 1] a = Variable('a') b = Variable('b') b_stop_grad = stop_gradient(3 * b) loss = MakeLoss(b_stop_grad + a)
executor = loss.simple_bind(ctx=cpu(), a=(1,2), b=(1,2)) executor.forward(is_train=True, a=v1, b=v2)
executor.outputs [ 1. 5.]
executor.backward() executor.grad_arrays [ 0. 0.] [ 1. 1.]

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L325

Value

- out: The result mx.ndarray
mx.nd.sum

Computes the sum of array elements over given axes.

Description

.. Note::

Arguments

data NDArray-or-Symbol The input
axis Shape or None, optional, default=None The axis or axes along which to perform the reduction.
The default, ‘axis=()’, will compute over all elements into a scalar array with shape ‘(1,)’.
If ‘axis’ is int, a reduction is performed on a particular axis.
If ‘axis’ is a tuple of ints, a reduction is performed on all the axes specified in the tuple.
If ‘exclude’ is true, reduction will be performed on the axes that are NOT in axis instead.
Negative values means indexing from right to left.
keepdims boolean, optional, default=0 If this is set to ‘True’, the reduced axes are left in the result as dimension with size one.
exclude boolean, optional, default=0 Whether to perform reduction on axis that are NOT in axis instead.

details

‘sam’ and ‘sum_axis’ are equivalent. For ndarray of csr storage type summation along axis 0 and axis 1 is supported. Setting keepdims or exclude to True will cause a fallback to dense operator.

Example::
data = [[[1, 2], [2, 3], [1, 3]], [[1, 4], [4, 3], [5, 2]], [[7, 1], [7, 2], [7, 3]]]
sum(data, axis=1) [[ 4. 8.] [10. 9.] [21. 6.]]
sum(data, axis=[1,2]) [12. 19. 27.]
data = [[1, 2, 0], [3, 0, 1], [4, 1, 0]]
csr = cast_storage(data, ‘csr’)
sum(csr, axis=0) [8. 3. 1.]
sum(csr, axis=1) [3. 4. 5.]
Defined in src/operator/tensor/broadcast_reduce_sum_value.cc:L67

value

out The result mx.ndarray
mx.nd.sum.axis

Computes the sum of array elements over given axes.

Description

.. Note::

Arguments

- **data**: NDArray-or-Symbol The input
- **axis**: Shape or None, optional, default=None The axis or axes along which to perform the reduction. The default, `axis=()`, will compute over all elements into a scalar array with shape `(1,)`. If `axis` is int, a reduction is performed on a particular axis. If `axis` is a tuple of ints, a reduction is performed on all the axes specified in the tuple. If `exclude` is true, reduction will be performed on the axes that are NOT in axis instead. Negative values means indexing from right to left.
- **keepdims**: boolean, optional, default=0 If this is set to ‘True’, the reduced axes are left in the result as dimension with size one.
- **exclude**: boolean, optional, default=0 Whether to perform reduction on axis that are NOT in axis instead.

Details

‘sum’ and ‘sum_axis’ are equivalent. For ndarray of csr storage type summation along axis 0 and axis 1 is supported. Setting keepdims or exclude to True will cause a fallback to dense operator.

Example::

```python
data = [[[1, 2], [2, 3], [1, 3]], [[1, 4], [4, 3], [5, 2]], [[7, 1], [7, 2], [7, 3]]]
sum(data, axis=1) [[ 4.  8.]] [ 10.  9.]] [ 21.  6.]]
sum(data, axis=[1,2]) [12.  19.  27.]
data = [[1, 2, 0], [3, 0, 1], [4, 1, 0]]
csr = cast_storage(data, 'csr')
sum(csr, axis=0) [ 8.  3.  1.]
sum(csr, axis=1) [ 3.  4.  5.]
```

Defined in src/operator/tensor/broadcast_reduce_sum_value.cc:L67

Value

- **out**: The result mx.ndarray
**mx.nd.SVMOutput**

*Computes support vector machine based transformation of the input.*

**Description**

This tutorial demonstrates using SVM as output layer for classification instead of softmax: https://github.com/dmlc/mxnet/tree/master/example/svm_mnist.

**Arguments**

- **data**: NDArray-or-Symbol Input data for SVM transformation.
- **label**: NDArray-or-Symbol Class label for the input data.
- **margin**: float, optional, default=1 The loss function penalizes outputs that lie outside this margin. Default margin is 1.
- **regularization.coefficient**: float, optional, default=1 Regularization parameter for the SVM. This balances the tradeoff between coefficient size and error.
- **use.linear**: boolean, optional, default=0 Whether to use L1-SVM objective. L2-SVM objective is used by default.

**Value**

- **out**: The result mx.ndarray

**mx.nd.swapaxes**

*Interchanges two axes of an array.*

**Description**

Examples::

**Arguments**

- **data**: NDArray-or-Symbol Input array.
- **dim1**: int, optional, default='0' the first axis to be swapped.
- **dim2**: int, optional, default='0' the second axis to be swapped.

**Details**

x = [[1, 2, 3]] swapaxes(x, 0, 1) = [[1], [2], [3]]

\nx = [[[0, 1], [2, 3]], [[4, 5], [6, 7]]] // (2,2,2) array

\nswapaxes(x, 0, 2) = [[[0, 4], [2, 6]], [[1, 5], [3, 7]]]

Defined in src/operator/swapaxis.cc:L70

**Value**

- **out**: The result mx.ndarray
**mx.nd.SwapAxis**

Interchanges two axes of an array.

**Description**

Examples::

**Arguments**

- **data**: NDArray-or-Symbol Input array.
- **dim1**: int, optional, default='0' the first axis to be swapped.
- **dim2**: int, optional, default='0' the second axis to be swapped.

**Details**

\[
\begin{align*}
x &= \begin{bmatrix}1 & 2 & 3\end{bmatrix} \\
\text{swapaxes}(x, 0, 1) &= \begin{bmatrix}1 \end{bmatrix}, \begin{bmatrix}2 \end{bmatrix}, \begin{bmatrix}3 \end{bmatrix}
\end{align*}
\]

\[
\begin{align*}
x &= \begin{bmatrix} \begin{bmatrix}0 & 1\end{bmatrix}, \begin{bmatrix}2 & 3\end{bmatrix} \end{bmatrix}, \begin{bmatrix} \begin{bmatrix}4 & 5\end{bmatrix}, \begin{bmatrix}6 & 7\end{bmatrix}\end{bmatrix} \end{bmatrix} \quad \text{(2x2,2) array}
\end{align*}
\]

\[
\text{swapaxes}(x, 0, 2) = \begin{bmatrix} \begin{bmatrix}0 & 4\end{bmatrix}, \begin{bmatrix}2 & 6\end{bmatrix} \end{bmatrix}, \begin{bmatrix} \begin{bmatrix}1 & 5\end{bmatrix}, \begin{bmatrix}3 & 7\end{bmatrix}\end{bmatrix}
\end{align*}
\]

Defined in src/operator/swapaxis.cc:L70

**Value**

- **out**: The result mx.ndarray

---

**mx.nd.take**

Takes elements from an input array along the given axis.

**Description**

This function slices the input array along a particular axis with the provided indices.

**Arguments**

- **a**: NDArray-or-Symbol The input array.
- **indices**: NDArray-or-Symbol The indices of the values to be extracted.
- **axis**: int, optional, default='0' The axis of input array to be taken. For input tensor of rank r, it could be in the range of [-r, r-1]
- **mode**: 'clip', 'raise', 'wrap', optional, default='clip' Specify how out-of-bound indices behave. Default is "clip". "clip" means clip to the range. So, if all indices mentioned are too large, they are replaced by the index that addresses the last element along an axis. "wrap" means to wrap around. "raise" means to raise an error when index out of range.
**Details**

Given data tensor of rank $r \geq 1$, and indices tensor of rank $q$, gather entries of the axis dimension of data (by default outer-most one as axis=0) indexed by indices, and concatenates them in an output tensor of rank $q + (r - 1)$.

Examples::

```python
x = [4. 5. 6.]
// Trivial case, take the second element along the first axis.
take(x, [1]) = [ 5. ]
// The other trivial case, axis=-1, take the third element along the first axis
take(x, [3], axis=-1, mode='clip') = [ 6. ]
x = [[ 1., 2.], [ 3., 4.], [ 5., 6.]]
// In this case we will get rows 0 and 1, then 1 and 2. Along axis 0
take(x, [[(0,1),(1,2)]]) = [[[ 1.], [ 3.]], [[ 2.], [ 4.]]]
[[ 3., 4.], [ 5., 6.]]
// In this case we will get rows 0 and 1, then 1 and 2 (calculated by wrapping around). // Along axis 1
take(x, [[(0, 3), [-1, -2]]], axis=1, mode='wrap') = [[[ 1.2.]], [[ 2.1.]]]
[[ 3. 4.], [ 4. 3.]]
[[ 5. 6.], [ 6. 5.]]
The storage type of “take” output depends upon the input storage type:
- take(default, default) = default
- take(csr, default, axis=0) = csr
```

Defined in src/operator/tensor/indexing_op.cc:L777

**Value**

out The result mx.ndarray

---

**mx.nd.tan**

*Computes the element-wise tangent of the input array.*

**Description**

The input should be in radians (\(2\pi\) rad equals 360 degrees).

**Arguments**

- **data**: NDArray-or-Symbol The input array.
mx.nd.tanh

Details

.. math:: \tan([0, \pi/4, \pi/2]) = [0, 1, -\infty]

The storage type of “tan” output depends upon the input storage type:
- \tan(default) = default - \tan(row_sparse) = row_sparse - \tan(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L140

Value

out The result mx.nd.array

mx.nd.tanh

Returns the hyperbolic tangent of the input array, computed element-wise.

Description

.. math:: \tanh(x) = \frac{\sinh(x)}{\cosh(x)}

Arguments

data NDArray-or-Symbol The input array.

Details

The storage type of “tanh” output depends upon the input storage type:
- \tanh(default) = default - \tanh(row_sparse) = row_sparse - \tanh(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L451

Value

out The result mx.nd.array
### mx.nd.tile

Repeats the whole array multiple times. If “reps” has length \(d\), and input array has dimension of \(n\). There are three cases: - \(n=d\). Repeat \(i\)-th dimension of the input by “reps[\(i\)]” times: \(x = [[1, 2, 3, 4], [1, 2, 3, 4]]\) tile(x, reps=(2,3)) = \(\begin{bmatrix} 1., 2., 1., 2., 3., 4., 3., 4., 3., 4., 3., 4. \\ 1., 2., 1., 2., 3., 4., 3., 4., 3., 4., 3., 4. \\ 1., 2., 1., 2., 3., 4., 3., 4., 3., 4., 3., 4. \\ 1., 2., 1., 2., 3., 4., 3., 4., 3., 4., 3., 4. \end{bmatrix}\) - \(n>d\). “reps” is promoted to length \(n\) by prepending 1’s to it. Thus for an input shape “(2,3)”, “repos=(2,)” is treated as “(1,2)”:: tile(x, reps=(2,)) = \(\begin{bmatrix} 1., 2., 1., 2. \\ 3., 4., 3., 4. \end{bmatrix}\) - \(n<d\). The input is promoted to be \(d\)-dimensional by prepending new axes. So a shape “(2,2)” array is promoted to “(1,2,2)” for 3-D replication:: tile(x, reps=(2,2,3)) = \(\begin{bmatrix} 1., 2., 1., 2., 1., 2., 3., 4., 3., 4., 3., 4. \\ 1., 2., 1., 2., 1., 2., 3., 4., 3., 4., 3., 4. \\ 1., 2., 1., 2., 1., 2., 3., 4., 3., 4., 3., 4. \end{bmatrix}\).  

#### Description

Defined in src/operator/tensor/matrix_op.cc:L796  

#### Arguments

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>NDArray-or-Symbol Input data array</td>
</tr>
<tr>
<td>reps</td>
<td>Shape(tuple), required The number of times for repeating the tensor a. Each dim size of reps must be a positive integer. If reps has length (d), the result will have dimension of max(d, a.ndim); If a.ndim &lt; d, a is promoted to be d-dimensional by prepending new axes. If a.ndim &gt; d, reps is promoted to a.ndim by prepending 1’s to it.</td>
</tr>

### mx.nd.topk

Returns the indices of the top \(k\) elements in an input array along the given axis (by default). If ret_type is set to ‘value’ returns the value of top \(k\) elements (instead of indices). In case of ret_type = ‘both’, both value and index would be returned. The returned elements will be sorted.

#### Description

Examples::
mx.nd.transpose

Arguments

data          NDArray-or-Symbol The input array
axis          int or None, optional, default='-1' Axis along which to choose the top k indices. If not given, the flattened array is used. Default is -1.
k          int, optional, default='1' Number of top elements to select, should be always smaller than or equal to the element number in the given axis. A global sort is performed if set k < 1.
ret.typ          'both', 'indices', 'mask', 'value'.optional, default='indices' The return type. "value" means to return the top k values, "indices" means to return the indices of the top k values, "mask" means to return a mask array containing 0 and 1. 1 means the top k values. "both" means to return a list of both values and indices of top k elements.
is.ascend          boolean, optional, default=0 Whether to choose k largest or k smallest elements. Top K largest elements will be chosen if set to false.
dtype          'float16', 'float32', 'float64', 'int32', 'int64', 'uint8',optional, default='float32' DType of the output indices when ret_typ is "indices" or "both". An error will be raised if the selected data type cannot precisely represent the indices.

Details

x = [[0.3, 0.2, 0.4], [0.1, 0.3, 0.2]]
// returns an index of the largest element on last axis topk(x) = [[2.], [1.]]
// returns the value of top-2 largest elements on last axis topk(x, ret_typ='value', k=2) = [[0.4, 0.3], [0.3, 0.2]]
// returns the value of top-2 smallest elements on last axis topk(x, ret_typ='value', k=2, is_ascend=1) = [[0.2, 0.3], [0.1, 0.2]]
// returns the value of top-2 largest elements on axis 0 topk(x, axis=0, ret_typ='value', k=2) = [[0.3, 0.3, 0.4], [0.1, 0.2, 0.2]]
// flattens and then returns list of both values and indices topk(x, ret_typ='both', k=2) = [[[0.4, 0.3], [0.3, 0.2]], [[2., 0.], [1., 2.]]]

Defined in src/operator/tensor/ordering_op.cc:L68

Value

out The result mx.ndarray

mx.nd.transpose  Permute the dimensions of an array. Examples::: x = [[1, 2], [3, 4]]
transpose(x, axes=(1,0,2)) = [[[1., 2.], [5., 6.]], [[3., 4.], [7., 8.]]]
mx.nd.trunc

Description

Defined in src/operator/tensor/matrix_op.cc:L328

Arguments

data NDArray-or-Symbol Source input
axes Shape(tuple), optional, default=[] Target axis order. By default the axes will be inverted.

Value

out The result mx.ndarray

mx.nd.trunc

Return the element-wise truncated value of the input.

Description

The truncated value of the scalar x is the nearest integer i which is closer to zero than x is. In short, the fractional part of the signed number x is discarded.

Arguments

data NDArray-or-Symbol The input array.

Details

Example::

trunc([-2.1, -1.9, 1.5, 1.9, 2.1]) = [-2., -1., 1., 1., 2.]

The storage type of “trunc“ output depends upon the input storage type:
- trunc(default) = default - trunc(row_sparse) = row_sparse - trunc(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L856

Value

out The result mx.ndarray
mx.nd.uniform

Draw random samples from a uniform distribution.

Description

.. note:: The existing alias “uniform” is deprecated.

Arguments

- **low**: float, optional, default=0 Lower bound of the distribution.
- **high**: float, optional, default=1 Upper bound of the distribution.
- **shape**: Shape(tuple), optional, default=None Shape of the output.
- **ctx**: string, optional, default='' Context of output, in format [cpu|gpu|cpu_pinned](n). Only used for imperative calls.
- **dtype**: 'None', 'float16', 'float32', 'float64', optional, default='None' Dtype of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).

Details

Samples are uniformly distributed over the half-open interval *[low, high)* (includes *low*, but excludes *high*).

Example::

    uniform(low=0, high=1, shape=(2,2)) = [[ 0.60276335, 0.85794562], [ 0.54488319, 0.84725171]]

Defined in src/operator/random/sample_op.cc:L96

Value

- **out** The result mx.ndarray

mx.nd.unravel.index

Converts an array of flat indices into a batch of index arrays. The operator follows numpy conventions so a single multi index is given by a column of the output matrix. The leading dimension may be left unspecified by using -1 as placeholder.

Description

Examples::

Arguments

- **data**: NDArray-or-Symbol Array of flat indices
- **shape**: Shape(tuple), optional, default=None Shape of the array into which the multi-indices apply.
Details

\[ A = [22,41,37] \text{ unravel}(A, \text{shape}=(7,6)) = [[3,6,6],[4,5,1]] \text{ unravel}(A, \text{shape}=(1,6)) = [[3,6,6],[4,5,1]] \]

Defined in src/operator/tensor/ravel.cc:L68

Value

out The result mx.ndarray

```
mx.nd.UpSampling

mx.nd.UpSampling
Upsamples the given input data.
```

Description

Two algorithms ("sample_type") are available for upsampling:

Arguments

data NDArray-or-Symbol[] Array of tensors to upsample. For bilinear upsampling, there should be 2 inputs - 1 data and 1 weight.
scale int, required Up sampling scale
num.filter int, optional, default='0' Input filter. Only used by bilinear sample_type. Since bilinear upsampling uses deconvolution, num_filters is set to the number of channels.
sample.type 'bilinear', 'nearest', required upsampling method
multi.input.mode 'concat', 'sum', optional, default='concat' How to handle multiple input. concat means concatenate upsampled images along the channel dimension. sum means add all images together, only available for nearest neighbor upsampling.
num.args int, required Number of inputs to be upsampled. For nearest neighbor upsampling, this can be 1-N; the size of output will be(scale*h_0,scale*w_0) and all other inputs will be upsampled to the same size. For bilinear upsampling this must be 2; 1 input and 1 weight.
workspace long (non-negative), optional, default=512 Tmp workspace for deconvolution (MB)

Details

- Nearest Neighbor - Bilinear

**Nearest Neighbor Upsampling**

Input data is expected to be NCHW.

Example::

\[ x = [[[1. 1. 1.] [1. 1. 1.] [1. 1. 1.]]] \]
UpSampling(x, scale=2, sample_type='nearest') = [[[1. 1. 1. 1. 1. 1.] [1. 1. 1. 1. 1. 1.] [1. 1. 1. 1. 1. 1.] [1. 1. 1. 1. 1. 1.] [1. 1. 1. 1. 1. 1.] [1. 1. 1. 1. 1. 1.]]]

**Bilinear Upsampling**

Uses ‘deconvolution’ algorithm under the hood. You need provide both input data and the kernel. Input data is expected to be NCHW.

‘num_filter’ is expected to be same as the number of channels.

Example::

x = [[[1. 1. 1.] [1. 1. 1.] [1. 1. 1.]]]
w = [[[1. 1. 1. 1.] [1. 1. 1. 1.] [1. 1. 1. 1.] [1. 1. 1. 1.]]]

UpSampling(x, w, scale=2, sample_type='bilinear', num_filter=1) = [[[1. 2. 2. 2. 2. 1.] [2. 4. 4. 4. 4. 2.] [2. 4. 4. 4. 4. 2.] [2. 4. 4. 4. 4. 2.] [2. 4. 4. 4. 4. 2.] [1. 2. 2. 2. 2. 1.]]]

Defined in src/operator/nn/upsampling.cc:L173

Value

out The result mx.ndarray

mx.nd.where

Return the elements, either from x or y, depending on the condition.

Description

Given three ndarrays, condition, x, and y, return an ndarray with the elements from x or y, depending on the elements from condition are true or false. x and y must have the same shape. If condition has the same shape as x, each element in the output array is from x if the corresponding element in the condition is true, and from y if false.

Arguments

condition NDArray-or-Symbol condition array
x NDArray-or-Symbol
y NDArray-or-Symbol

Details

If condition does not have the same shape as x, it must be a 1D array whose size is the same as x’s first dimension size. Each row of the output array is from x’s row if the corresponding element from condition is true, and from y’s row if false.

Note that all non-zero values are interpreted as “True” in condition.

Examples::

x = [[1, 2], [3, 4]] y = [[5, 6], [7, 8]] cond = [[0, 1], [-1, 0]]

where(cond, x, y) = [[5, 2], [3, 8]]
csr_cond = cast_storage(cond, 'csr')
where(csr_cond, x, y) = [[5, 2], [3, 8]]
Defined in src/operator/tensor/control_flow_op.cc:L57

**Value**

*out* The result *mx.ndarray*

---

**mx.nd.zeros**

*Generate an mx.nd.array object with zeros*

---

**Description**

Generate an mx.nd.array object with zeros

**Usage**

`mx.nd.zeros(shape, ctx = NULL)`

**Arguments**

- **shape**: the dimension of the *mx.nd.array*
- **ctx**: optional The context device of the array. `mx.ctx.default()` will be used in default.

**Examples**

```python
mat = mx.nd.zeros(10)
as.array(mat)
mat2 = mx.nd.zeros(c(5,5))
as.array(mat)
mat3 = mx.nd.zeros(c(3,3,3))
as.array(mat3)
```

---

**mx.nd.zeros_like**

*Return an array of zeros with the same shape, type and storage type as the input array.*

---

**Description**

The storage type of “zeros_like“ output depends on the storage type of the input

**Arguments**

- **data**: NDArray-or-Symbol The input
mx.opt.adadelta

Details

- zeros_like(row_sparse) = row_sparse - zeros_like(csr) = csr - zeros_like(default) = default

Examples:

x = [[ 1., 1., 1.], [ 1., 1., 1.]]
zeros_like(x) = [[ 0., 0., 0.], [ 0., 0., 0.]]

Value

out The result mx.ndarray

mx.opt.adadelta  Create an AdaDelta optimizer with respective parameters.

Description

Usage

mx.opt.adadelta(
    rho = 0.9,
    epsilon = 1e-05,
    wd = 0,
    rescale.grad = 1,
    clip_gradient = -1
)

Arguments

rho  float, default=0.90 Decay rate for both squared gradients and delta x.
epsilon  float, default=1e-5 The constant as described in the thesis.
wd  float, default=0.0 L2 regularization coefficient add to all the weights.
rescale.grad  float, default=1 rescaling factor of gradient.
clip_gradient  float, default=-1 (no clipping if < 0) clip gradient in range [-clip_gradient, clip_gradient].
mx.opt.adagrad

Create an AdaGrad optimizer with respective parameters. AdaGrad optimizer of Duchi et al., 2011.

Description

This code follows the version in http://arxiv.org/pdf/1212.5701v1.pdf Eq(5) by Matthew D. Zeiler, 2012. AdaGrad will help the network to converge faster in some cases.

Usage

mx.opt.adagrad(
    learning.rate = 0.05,
    epsilon = 1e-08,
    wd = 0,
    rescale.grad = 1,
    clip_gradient = -1,
    lr_scheduler = NULL
)

Arguments

learning.rate float, default=0.05 Step size.
epsilon float, default=1e-8
wd float, default=0.0 L2 regularization coefficient add to all the weights.
rescale.grad float, default=1.0 rescaling factor of gradient.
clip_gradient float, default=-1.0 (no clipping if < 0) clip gradient in range [-clip_gradient, clip_gradient].
lr_scheduler function, optional The learning rate scheduler.

mx.opt.adam

Create an Adam optimizer with respective parameters. Adam optimizer as described in [King2014].

Description

Usage

```python
mx.opt.adam(
    learning_rate = 0.001,
    beta1 = 0.9,
    beta2 = 0.999,
    epsilon = 1e-08,
    wd = 0,
    rescale_grad = 1,
    clip_gradient = -1,
    lr_scheduler = NULL
)
```

Arguments

- `learning_rate` : float, default=1e-3 The initial learning rate.
- `beta1` : float, default=0.9 Exponential decay rate for the first moment estimates.
- `beta2` : float, default=0.999 Exponential decay rate for the second moment estimates.
- `epsilon` : float, default=1e-8
- `wd` : float, default=0.0 L2 regularization coefficient add to all the weights.
- `rescale_grad` : float, default=1.0 rescaling factor of gradient.
- `clip_gradient` : float, optional, default=-1 (no clipping if < 0) clip gradient in range [-clip_gradient, clip_gradient].
- `lr_scheduler` : function, optional The learning rate scheduler.

mx.opt.create

Create an optimizer by name and parameters

Description

Create an optimizer by name and parameters

Usage

```python
mx.opt.create(name, ...)
```

Arguments

- `name` : The name of the optimizer
- `...` : Additional arguments
Get an updater closure that can take list of weight and gradient and return updated list of weight.

**Usage**

```python
mx.opt.get_updater(optimizer, weights, ctx)
```

**Arguments**

- `optimizer` (required) The optimizer
- `weights` (required) The weights to be optimized

Create a Nesterov Accelerated SGD (NAG) optimizer.

**Description**

**Usage**

```python
mx.opt.nag(
    learning.rate = 0.01,
    momentum = 0,
    wd = 0,
    rescale.grad = 1,
    clip_gradient = -1,
    lr_scheduler = NULL
)
```

**Arguments**

- `learning.rate` (float, default=0.01) The initial learning rate.
- `momentum` (float, default=0) The momentum value.
- `wd` (float, default=0.0) L2 regularization coefficient added to all the weights.
- `rescale.grad` (float, default=1.0) Rescaling factor of gradient.
- `clip_gradient` (float, optional, default=-1) Clip gradient in range [-clip_gradient, clip_gradient].
- `lr_scheduler` (function, optional) The learning rate scheduler.
mx.opt.rmsprop

Description

Usage

mx.opt.rmsprop(
    learning.rate = 0.002,
    centered = TRUE,
    gamma1 = 0.95,
    gamma2 = 0.9,
    epsilon = 1e-04,
    wd = 0,
    rescale.grad = 1,
    clip_gradient = -1,
    lr_scheduler = NULL
)

Arguments

learning.rate float, default=0.002 The initial learning rate.
gamma1 float, default=0.95 decay factor of moving average for gradient, gradient^2.
gamma2 float, default=0.9 "momentum" factor.
epsilon float, default=1e-4
wd float, default=0.0 L2 regularization coefficient add to all the weights.
rescale.grad float, default=1.0 rescaling factor of gradient.
clip_gradient float, optional, default=-1 (no clipping if < 0) clip gradient in range [-clip_gradient, clip_gradient].
lr_scheduler function, optional The learning rate scheduler.
mx.opt.sgd  

Create an SGD optimizer with respective parameters. Perform SGD with momentum update

Description

Create an SGD optimizer with respective parameters. Perform SGD with momentum update

Usage

    mx.opt.sgd(
        learning.rate = 0.01,
        momentum = 0,
        wd = 0,
        rescale.grad = 1,
        clip_gradient = -1,
        lr_scheduler = NULL
    )

Arguments

    learning.rate  float, default=0.01 The initial learning rate.
    momentum      float, default=0 The momentum value
    wd            float, default=0.0 L2 regularization coefficient add to all the weights.
    rescale.grad  float, default=1.0 rescaling factor of gradient.
    clip_gradient float, optional, default=-1 (no clipping if < 0) clip gradient in range [-clip_gradient, clip_gradient].
    lr_scheduler  function, optional The learning rate scheduler.

mx.profiler.config  

Set up the configuration of profiler.

Description

Set up the configuration of profiler.

Usage

    mx.profiler.config(params)
mx.profiler.state

Arguments

flags list of key/value pair tuples. Indicates configuration parameters profile_symbolic : boolean, whether to profile symbolic operators profile_imperative : boolean, whether to profile imperative operators profile_memory : boolean, whether to profile memory usage profile_api : boolean, whether to profile the C API file_name : string, output file for profile data continuous_dump : boolean, whether to periodically dump profiling data to file dump_period : float, seconds between profile data dumps

mx.profiler.state Set up the profiler state to record operator.

Description

Set up the profiler state to record operator.

Usage

mx.profiler.state(state = MX.PROF.STATE$STOP)

Arguments

state Indicating whether to run the profiler, can be 'MX.PROF.STATE$RUN' or 'MX.PROF.STATE$STOP'. Default is 'MX.PROF.STATE$STOP'.
filename The name of output trace file. Default is 'profile.json'

mx.rnorm Generate normal distribution with mean and sd.

Description

Generate normal distribution with mean and sd.

Usage

mx.rnorm(shape, mean = 0, sd = 1, ctx = NULL)

Arguments

shape Dimension, The shape(dimension) of the result.
mean numeric, The mean of distribution.
sd numeric, The standard deviations.
ctx, optional The context device of the array. mx.ctx.default() will be used in default.
Examples

```r
mx.set.seed(0)
as.array(mx.runif(2))
# 0.5488135 0.5928446
mx.set.seed(0)
as.array(mx.rnorm(2))
# 2.212206 1.163079
```

**mx.runif**

Generate uniform distribution in \([low, high)\) with specified shape.

**Usage**

```r
mx.runif(shape, min = 0, max = 1, ctx = NULL)
```

**Arguments**

- `shape`: Dimension, The shape(dimension) of the result.
- `min`: numeric, The lower bound of distribution.
- `max`: numeric, The upper bound of distribution.
- `ctx`, optional: The context device of the array. `mx.ctx.default()` will be used in default.

**Examples**

```r
mx.set.seed(0)
as.array(mx.runif(2))
# 0.5488135 0.5928446
mx.set.seed(0)
as.array(mx.rnorm(2))
# 2.212206 1.163079
```
mx.serialize

Serialize MXNet model into RData-compatible format.

Description
Serializes MXNet model into RData-compatible format.

Usage
mx.serialize(model)

Arguments
model The mxnet model

mx.set.seed
Set the seed used by mxnet device-specific random number generators.

Description
Set the seed used by mxnet device-specific random number generators.

Usage
mx.set.seed(seed)

Arguments
seed the seed value to the device random number generators.

Details
We have a specific reason why mx.set.seed is introduced, instead of simply use set.seed. The reason that is that most of mxnet random number generator can run on different devices, such as GPU. We need to use massively parallel PRNG on GPU to get fast random number generations. It can also be quite costly to seed these PRNGs. So we introduced mx.set.seed for mxnet specific device random numbers.

Examples
mx.set.seed(0)
as.array(mx.runif(2))
# 0.5488135 0.5928446
mx.set.seed(0)
as.array(mx.rnorm(2))
# 2.212206 1.163079
**mx.simple.bind**

*Simple bind the symbol to executor, with information from input shapes.*

**Description**

Simple bind the symbol to executor, with information from input shapes.

**Usage**

```
mx.simple.bind(symbol, ctx, grad.req = "null", fixed.param = NULL, ...)
```

**mx.symbol.abs**

*abs:Returns element-wise absolute value of the input.*

**Description**

Example:

**Usage**

```
mx.symbol.abs(...)  
```

**Arguments**

- **data**
  - NDArray-or-Symbol: The input array.

- **name**
  - string, optional: Name of the resulting symbol.

**Details**

abs([-2, 0, 3]) = [2, 0, 3]

The storage type of “abs” output depends upon the input storage type:

- abs(default) = default - abs(row_sparse) = row_sparse - abs(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L720

**Value**

- **out** The result mx.symbol
mx.symbol.Activation

Activation: Applies an activation function element-wise to the input.

### Description

The following activation functions are supported:

### Usage

```python
mx.symbol.Activation(...)```

### Arguments

- **data**: NDArray-or-Symbol The input array.
- **act.type**: 'relu', 'sigmoid', 'softrelu', 'softsign', 'tanh', required Activation function to be applied.
- **name**: string, optional Name of the resulting symbol.

### Details

- 'relu': Rectified Linear Unit, \( y = \max(x, 0) \)
- 'sigmoid': \( y = \frac{1}{1 + \exp(-x)} \)
- 'tanh': Hyperbolic tangent, \( y = \frac{\exp(x) - \exp(-x)}{\exp(x) + \exp(-x)} \)
- 'softrelu': Soft ReLU, or SoftPlus, \( y = \log(1 + \exp(x)) \)
- 'softsign': \( y = \frac{x}{1 + \abs(x)} \)

Defined in src/operator/nn/activation.cc:L165

### Value

- **out**: The result mx.symbol

---

mx.symbol.adam_update

adam_update: Update function for Adam optimizer. Adam is seen as a generalization of AdaGrad.

### Description

Adam update consists of the following steps, where \( g \) represents gradient and \( m, v \) are 1st and 2nd order moment estimates (mean and variance).

### Usage

```python
mx.symbol.adam_update(...)```
Arguments

- **weight**: NDArray-or-Symbol Weight
- **grad**: NDArray-or-Symbol Gradient
- **mean**: NDArray-or-Symbol Moving mean
- **var**: NDArray-or-Symbol Moving variance
- **lr**: float, required Learning rate
- **beta1**: float, optional, default=0.899999976 The decay rate for the 1st moment estimates.
- **beta2**: float, optional, default=0.999000013 The decay rate for the 2nd moment estimates.
- **epsilon**: float, optional, default=9.99999994e-09 A small constant for numerical stability.
- **wd**: float, optional, default=0 Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
- **rescale.grad**: float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
- **clip.gradient**: float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient] If clip_gradient <= 0, gradient clipping is turned off. \( \text{grad} = \max(\min(\text{grad}, \text{clip}\_\text{gradient}), -\text{clip}\_\text{gradient}) \).
- **lazy.update**: boolean, optional, default=1 If true, lazy updates are applied if gradient’s stype is row_sparse and all of w, m and v have the same stype
- **name**: string, optional Name of the resulting symbol.

Details

.. math::
   g_t = \nabla J(W_{t-1})
   m_t = \beta_1 m_{t-1} + (1 - \beta_1) g_t
   v_t = \beta_2 v_{t-1} + (1 - \beta_2) g_t^2
   W_t = W_{t-1} - \alpha \frac{m_t}{\sqrt{v_t} + \epsilon}

It updates the weights using::

\[ m = \beta_1 m + (1-\beta_1) \text{grad} \]
\[ v = \beta_2 v + (1-\beta_2) (\text{grad}^2) \]
\[ w += - \text{learning_rate} \frac{m}{(\text{sqrt}(v) + \epsilon)} \]

However, if grad’s storage type is “row_sparse” and “lazy_update” is True and the storage type of weight is the same as those of m and v, only the row slices whose indices appear in grad.indices are updated (for w, m and v):::

for row in grad.indices:
   m[row] = beta1*m[row] + (1-beta1)*grad[row]
   v[row] = beta2*v[row] + (1-beta2)*(grad[row]**2)
   w[row] += - learning_rate * m[row] / (sqrt(v[row]) + epsilon)

Defined in src/operator/optimizer_op.cc:L688

Value

out The result mx.symbol
**mx.symbol.add_n**  
**add_n**: Adds all input arguments element-wise.

**Description**

.. math:: \text{add\_n}(a_1, a_2, ..., a_n) = a_1 + a_2 + ... + a_n

**Usage**

```python
mx.symbol.add_n(...)```

**Arguments**

- **args**: NDArray-or-Symbol[] Positional input arguments
- **name**: string, optional Name of the resulting symbol.

**Details**

“add_n“ is potentially more efficient than calling “add“ by ‘n‘ times.  
The storage type of “add_n“ output depends on storage types of inputs  
- add_n(row_sparse, row_sparse, ..) = row_sparse  
- add_n(default, csr, default) = default  
- add_n(any input combinations longer than 4 (>4) with at least one default type) = default  
- otherwise, “add_n“ falls all inputs back to default storage and generates default storage  

Defined in src/operator/tensor/elemwise_sum.cc:L156

**Value**

```python
out The result mx.symbol```

---

**mx.symbol.all_finite**  
**all_finite**: Check if all the float numbers in the array are finite (used for AMP)

**Description**

Defined in src/operator/contrib/all_finite.cc:L101

**Usage**

```python
mx.symbol.all_finite(...)```

**Arguments**

- **data**: NDArray Array
- **init.output**: boolean, optional, default=1 Initialize output to 1.
- **name**: string, optional Name of the resulting symbol.
mx.symbol.amp_cast

Value
  out The result mx.symbol

Description
  It casts only between low precision float/FP32 and does not do anything for other types.

Usage
  mx.symbol.amp_cast(...)
mx.symbol.arccos

Arguments

- **data**: NDArray-or-Symbol[] Weights
- **num.outputs**: int, required Number of input/output pairs to be casted to the widest type.
- **cast.narrow**: boolean, optional, default=0 Whether to cast to the narrowest type
- **name**: string, optional Name of the resulting symbol.

Details

Defined in src/operator/tensor/amp_cast.cc:L165

Value

- **out**: The result mx.symbol

---

mx.symbol.arccos  

arccos: Returns element-wise inverse cosine of the input array.

Description

The input should be in range ‘[-1, 1]’. The output is in the closed interval :math:`[0, \pi]`

Usage

```python
mx.symbol.arccos(...)
```

Arguments

- **data**: NDArray-or-Symbol The input array.
- **name**: string, optional Name of the resulting symbol.

Details

.. math:: \text{arccos}([-1, -0.707, 0, 0.707, 1]) = [\pi, 3\pi/4, \pi/2, \pi/4, 0]

The storage type of “arccos” output is always dense

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L233

Value

- **out**: The result mx.symbol
mx.symbol.arccosh

arccosh: Returns the element-wise inverse hyperbolic cosine of the input array, computed element-wise.

Description
The storage type of "arccosh" output is always dense

Usage
mx.symbol.arccosh(...)  

Arguments
- **data**: NDArray-or-Symbol The input array.
- **name**: string, optional Name of the resulting symbol.

Details
Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L535

Value
out The result mx.symbol

mx.symbol.arcsin

arcsin: Returns element-wise inverse sine of the input array.

Description
The input should be in the range ‘[-1, 1]’. The output is in the closed interval of [:math:`-\pi/2`, :math:`\pi/2`].

Usage
mx.symbol.arcsin(...)  

Arguments
- **data**: NDArray-or-Symbol The input array.
- **name**: string, optional Name of the resulting symbol.
mx.symbol.arcsinh

Details

.. math:: \text{arcsin}([-1, -0.707, 0, 0.707, 1]) = [-\frac{\pi}{2}, -\frac{\pi}{4}, 0, \frac{\pi}{4}, \frac{\pi}{2}]

The storage type of “arcsin” output depends upon the input storage type:
- arcsin(default) = default - arcsin(row_sparse) = row_sparse - arcsin(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L187

Value

out The result mx.symbol

mx.symbol.arcsinh

arcsinh: Returns the element-wise inverse hyperbolic sine of the input array, computed element-wise.

Description

The storage type of “arcsinh” output depends upon the input storage type:

Usage

mx.symbol.arcsinh(...)

Arguments

data NDArray-or-Symbol The input array.

name string, optional Name of the resulting symbol.

Details

- arcsinh(default) = default - arcsinh(row_sparse) = row_sparse - arcsinh(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L494

Value

out The result mx.symbol
mx.symbol.arctan

\textbf{arctan: Returns element-wise inverse tangent of the input array.}

\textbf{Description}

The output is in the closed interval :math:`[-\pi/2, \pi/2]`.

\textbf{Usage}

\texttt{mx.symbol.arctan(\ldots)}

\textbf{Arguments}

- \texttt{data} : NDArray-or-Symbol The input array.
- \texttt{name} : string, optional Name of the resulting symbol.

\textbf{Details}

.. math::
   \text{arctan}([-1, 0, 1]) = [-\pi/4, 0, \pi/4]

The storage type of “arctan” output depends upon the input storage type:
- arctan(default) = default
- arctan(row_sparse) = row_sparse
- arctan(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L282

\textbf{Value}

\texttt{out} The result \texttt{mx.symbol}

mx.symbol.arctanh

\textbf{arctanh: Returns the element-wise inverse hyperbolic tangent of the input array, \textbackslash computed element-wise.}

\textbf{Description}

The storage type of “arctanh” output depends upon the input storage type:

\textbf{Usage}

\texttt{mx.symbol.arctanh(\ldots)}

\textbf{Arguments}

- \texttt{data} : NDArray-or-Symbol The input array.
- \texttt{name} : string, optional Name of the resulting symbol.
mx.symbol.argmax

Details
- `arctanh(default) = default - arctanh(row_sparse) = row_sparse - arctanh(csr) = csr`

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L579

Value
out The result mx.symbol

---

mx.symbol.argmax

argmax: Returns indices of the maximum values along an axis.

Description
In the case of multiple occurrences of maximum values, the indices corresponding to the first occurrence are returned.

Usage
mx.symbol.argmax(...)

Arguments
- **data**: NDArray-or-Symbol The input
- **axis**: int or None, optional, default=`None` The axis along which to perform the reduction. Negative values means indexing from right to left. “Requires axis to be set as int, because global reduction is not supported yet.”
- **keepdims**: boolean, optional, default=0 If this is set to ‘True’, the reduced axis is left in the result as dimension with size one.
- **name**: string, optional Name of the resulting symbol.

Details
Examples:
x = [[0., 1., 2.], [3., 4., 5.]]
// argmax along axis 0 argmax(x, axis=0) = [1., 1., 1.]
// argmax along axis 1 argmax(x, axis=1) = [2., 2.]
// argmax along axis 1 keeping same dims as an input array argmax(x, axis=1, keepdims=True) = [[2.], [2.]]

Defined in src/operator/tensor/broadcast_reduce_op_index.cc:L52

Value
out The result mx.symbol
mx.symbol.argmax_channel
argmax_channel: Returns argmax indices of each channel from the input array.

Description
The result will be an NDArray of shape (num_channel,).

Usage
mx.symbol.argmax_channel(...)

Arguments
- data: NDArray-or-Symbol The input array
- name: string, optional Name of the resulting symbol.

Details
In case of multiple occurrences of the maximum values, the indices corresponding to the first occurrence are returned.

Examples:
x = [[ 0., 1., 2.], [ 3., 4., 5.]]
argmax_channel(x) = [ 2., 2.]
Defined in src/operator/tensor/broadcast_reduce_op_index.cc:L97

Value
out The result mx.symbol

mx.symbol.argmin
argmin: Returns indices of the minimum values along an axis.

Description
In the case of multiple occurrences of minimum values, the indices corresponding to the first occurrence are returned.

Usage
mx.symbol.argmin(...)
mx.symbol.argsort

Arguments

- **data**: NDArray-or-Symbol. The input.
- **axis**: int or None, optional, default='None'. The axis along which to perform the reduction. Negative values means indexing from right to left. "Requires axis to be set as int, because global reduction is not supported yet."
- **keepdims**: boolean, optional, default=0. If this is set to 'True', the reduced axis is left in the result as dimension with size one.
- **name**: string, optional. Name of the resulting symbol.

Details

Examples:

```python
x = [[ 0., 1., 2.], [ 3., 4., 5.]]
// argmin along axis 0
argmin(x, axis=0) = [ 0., 0., 0.]
// argmin along axis 1
argmin(x, axis=1) = [ 0., 0.]
// argmin along axis 1 keeping same dims as an input array
argmin(x, axis=1, keepdims=True) = [[ 0.], [ 0.]]
```

Defined in `src/operator/tensor/broadcast_reduce_op_index.cc:L77`

Value

- **out**: The result mx.symbol

```
mx.symbol.argsort .argsort:Returns the indices that would sort an input array along the given axis.
```

Description

This function performs sorting along the given axis and returns an array of indices having same shape as an input array that index data in sorted order.

Usage

- `mx.symbol.argsort(...)`

Arguments

- **data**: NDArray-or-Symbol. The input array.
- **axis**: int or None, optional, default=-1. Axis along which to sort the input tensor. If not given, the flattened array is used. Default is -1.
- **is.ascend**: boolean, optional, default=1. Whether to sort in ascending or descending order.
mx.symbol.BatchNorm

BatchNorm: Batch normalization.

Description

Normalizes a data batch by mean and variance, and applies a scale “gamma” as well as offset “beta”.

Usage

mx.symbol.BatchNorm(...)

Arguments

data: NDArray-or-Symbol Input data to batch normalization

gamma: NDArray-or-Symbol gamma array

beta: NDArray-or-Symbol beta array

moving.mean: NDArray-or-Symbol running mean of input

moving.var: NDArray-or-Symbol running variance of input

eps: double, optional, default=0.0010000000474974513 Epsilon to prevent div 0. Must be no less than CUDNN_BN_MIN_EPSILON defined in cudnn.h when using cudnn (usually 1e-5)

momentum: float, optional, default=0.899999976 Momentum for moving average

fix.gamma: boolean, optional, default=1 Fix gamma while training

DType of the output indices. It is only valid when ret_typ is "indices" or "both". An error will be raised if the selected data type cannot precisely represent the indices.

name: string, optional Name of the resulting symbol.

Examples:

```python
x = [[ 0.3, 0.2, 0.4], [ 0.1, 0.3, 0.2]]
// sort along axis -1
argsort(x) = [[ 1., 0., 2.], [ 0., 2., 1.]]

// sort along axis 0
argsort(x, axis=0) = [[ 1., 0., 1.], [ 0., 1., 0.]]

// flatten and then sort
argsort(x, axis=None) = [ 3., 1., 5., 0., 4., 2.]
```

Defined in src/operator/tensor/ordering_op.cc:L185
**use.global.stats**

boolean, optional, default=0 Whether use global moving statistics instead of local batch-norm. This will force change batch-norm into a scale shift operator.

**output.mean.var**

boolean, optional, default=0 Output the mean and inverse std

**axis**

int, optional, default=1 Specify which shape axis the channel is specified

**cudnn.off**

boolean, optional, default=0 Do not select CUDNN operator, if available

**min.calib.range**

float or None, optional, default=None The minimum scalar value in the form of float32 obtained through calibration. If present, it will be used to by quantized batch norm op to calculate primitive scale. Note: this calib_range is to calib bn output.

**max.calib.range**

float or None, optional, default=None The maximum scalar value in the form of float32 obtained through calibration. If present, it will be used to by quantized batch norm op to calculate primitive scale. Note: this calib_range is to calib bn output.

**name**

string, optional Name of the resulting symbol.

**Details**

Assume the input has more than one dimension and we normalize along axis 1. We first compute the mean and variance along this axis:

\[
\text{data\_mean}[i] = \text{mean}(\text{data[:,i,:,:...])}
\]

\[
\text{data\_var}[i] = \text{var}(\text{data[:,i,:,:...])}
\]

Then compute the normalized output, which has the same shape as input, as following:

\[
\text{out[:,i,:,:...]} = \frac{\text{data[:,i,:,:...]} - \text{data\_mean}[i]\sqrt{\text{data\_var}[i]+\epsilon}}{\gamma[i]} + \beta[i]
\]

Both \*mean\* and \*var\* returns a scalar by treating the input as a vector.

Assume the input has size \*k\* on axis 1, then both “gamma” and “beta” have shape \*(k,)*. If “output_mean_var” is set to be true, then outputs both “data_mean” and the inverse of “data_var”, which are needed for the backward pass. Note that gradient of these two outputs are blocked.

Besides the inputs and the outputs, this operator accepts two auxiliary states, “moving_mean” and “moving_var”, which are \*k\*-length vectors. They are global statistics for the whole dataset, which are updated by:

\[
\text{moving\_mean} = \text{moving\_mean} \times \text{momentum} + \text{data\_mean} \times (1 - \text{momentum})
\]

\[
\text{moving\_var} = \text{moving\_var} \times \text{momentum} + \text{data\_var} \times (1 - \text{momentum})
\]

If “use_global_stats” is set to be true, then “moving_mean” and “moving_var” are used instead of “data_mean” and “data_var” to compute the output. It is often used during inference.

The parameter “axis” specifies which axis of the input shape denotes the ‘channel’ (separately normalized groups). The default is 1. Specifying -1 sets the channel axis to be the last item in the input shape.

Both “gamma” and “beta” are learnable parameters. But if “fix_gamma” is true, then set “gamma” to 1 and its gradient to 0.
mx.symbol.BatchNorm_v1

.. Note:: When “fix_gamma” is set to True, no sparse support is provided. If “fix_gamma” is” set to False, the sparse tensors will fallback.
Defined in src/operator/nn/batch_norm.cc:L607

Value

out The result mx.symbol

mx.symbol.BatchNorm_v1

BatchNorm_v1:Batch normalization.

Description

This operator is DEPRECATED. Perform BatchNorm on the input.

Usage

mx.symbol.BatchNorm_v1(...)

Arguments

data NDArray-or-Symbol Input data to batch normalization
gamma NDArray-or-Symbol gamma array
beta NDArray-or-Symbol beta array
eps float, optional, default=0.00100000005 Epsilon to prevent div 0
momentum float, optional, default=0.899999976 Momentum for moving average
fix.gamma boolean, optional, default=1 Fix gamma while training
use.global.stats boolean, optional, default=0 Whether use global moving statistics instead of local batch-norm. This will force change batch-norm into a scale shift operator.
output.mean.var boolean, optional, default=0 Output All,normal mean and var
name string, optional Name of the resulting symbol.

Details

Normalizes a data batch by mean and variance, and applies a scale “gamma“ as well as offset “beta“. Assume the input has more than one dimension and we normalize along axis 1. We first compute the mean and variance along this axis:

.. math::
data\_mean[i] = mean(data[:,i,:,:,...]) \ data\_var[i] = var(data[:,i,:,:,...])

Then compute the normalized output, which has the same shape as input, as following:
.. math::
   \text{out}[:,i,:,\ldots] = \frac{\text{data}[:,i,:,\ldots]}{\sqrt{\text{data}_\text{var}[i]}} + \epsilon \cdot \gamma[i] + \beta[i]

Both *mean* and *var* returns a scalar by treating the input as a vector.

Assume the input has size *k* on axis 1, then both “gamma” and “beta” have shape *(k,)*. If
“output_mean_var” is set to be true, then outputs both “data_mean” and “data_var” as well, which
are needed for the backward pass.

Besides the inputs and the outputs, this operator accepts two auxiliary states, “moving_mean” and
“moving_var”, which are *k*-length vectors. They are global statistics for the whole dataset, which
are updated by:

   moving_mean = moving_mean * momentum + data_mean * (1 - momentum)  
   moving_var = moving_var * momentum + data_var * (1 - momentum)

If “use_global_stats” is set to be true, then “moving_mean” and “moving_var” are used instead of
“data_mean” and “data_var” to compute the output. It is often used during inference.

Both “gamma” and “beta” are learnable parameters. But if “fix_gamma” is true, then set “gamma”
to 1 and its gradient to 0.

There’s no sparse support for this operator, and it will exhibit problematic behavior if used with
sparse tensors.

Defined in src/operator/batch_norm_v1.cc:L95

**Value**

out The result mx.symbol

---

**mx.symbol.batch_dot**  
**batch_dot**: Batchwise dot product.

**Description**

“batch_dot” is used to compute dot product of “x” and “y” when “x” and “y” are data in batch,
namely N-D (N >= 3) arrays in shape of ‘(B0, ..., B_i, :, :)'.

**Usage**

mx.symbol.batch_dot(...)

**Arguments**

- **lhs**: NDArray-or-Symbol The first input
- **rhs**: NDArray-or-Symbol The second input
- **transpose.a**: boolean, optional, default=0 If true then transpose the first input before dot.
- **transpose.b**: boolean, optional, default=0 If true then transpose the second input before dot.
- **forward.stype**: None, ‘csr’, ‘default’, ‘row_sparse’, optional, default=’None’ The desired storage type of the forward output given by user, if the combination of input storage types and this hint does not match any implemented ones, the dot operator will perform fallback operation and still produce an output of the desired storage type.
- **name**: string, optional Name of the resulting symbol.
mx.symbol.batch_take

batch_take:Takes elements from a data batch.

Description

.. note:: ‘batch_take’ is deprecated. Use ‘pick’ instead.

Usage

mx.symbol.batch_take(...)  # Arguments

Arguments

a  NDArray-or-Symbol The input array
indices  NDArray-or-Symbol The index array
name  string, optional Name of the resulting symbol.

Details

Given an input array of shape “(d0, d1)” and indices of shape “(i0,)”, the result will be an output array of shape “(i0,)” with:

output[i] = input[i, indices[i]]

Examples:

x = [[ 1., 2.], [ 3., 4.], [ 5., 6.]]

// takes elements with specified indices batch_take(x, [0,1,0]) = [ 1. 4. 5.]

Defined in src/operator/tensor/indexing_op.cc:L836

Value

out The result mx.symbol
**mx.symbol.BilinearSampler**

**BilinearSampler:** Applies bilinear sampling to input feature map.

---

**Description**

Bilinear Sampling is the key of [NIPS2015] "Spatial Transformer Networks". The usage of the operator is very similar to remap function in OpenCV, except that the operator has the backward pass.

**Usage**

```python
mx.symbol.BilinearSampler(...)
```

**Arguments**

- **data**: NDArray-or-Symbol Input data to the BilinearSamplerOp.
- **grid**: NDArray-or-Symbol Input grid to the BilinearSamplerOp. grid has two channels: x_src, y_src
- **cudnn.off**: boolean or None, optional, default=None whether to turn cudnn off
- **name**: string, optional Name of the resulting symbol.

**Details**

Given :math:`data` and :math:`grid`, then the output is computed by

.. math::
   \begin{align*}
   x_{src} &= grid[batch, 0, y_{dst}, x_{dst}] \backslash
   y_{src} &= grid[batch, 1, y_{dst}, x_{dst}] \backslash
   output[batch, channel, y_{dst}, x_{dst}] &= G(data[batch, channel, y_{src}, x_{src}])
   \end{align*}

:math:`x_{dst}`, :math:`y_{dst}` enumerate all spatial locations in :math:`output`, and :math:`G()` denotes the bilinear interpolation kernel. The out-boundary points will be padded with zeros. The shape of the output will be (data.shape[0], data.shape[1], grid.shape[2], grid.shape[3]).

The operator assumes that :math:`data` has 'NCHW' layout and :math:`grid` has been normalized to [-1, 1].

BilinearSampler often cooperates with GridGenerator which generates sampling grids for BilinearSampler. GridGenerator supports two kinds of transformation: "affine" and "warp". If users want to design a CustomOp to manipulate :math:`grid`, please firstly refer to the code of GridGenerator.

**Example 1:**

```python
## Zoom out data two times data = array([[[[1, 4, 3, 6], [1, 8, 8, 9], [0, 4, 1, 5], [1, 0, 1, 3]]]])
affine_matrix = array([[2, 0, 0], [0, 2, 0]])
affine_matrix = reshape(affine_matrix, shape=(1, 6))
grid = GridGenerator(data=affine_matrix, transform_type='affine', target_shape=(4, 4))
out = BilinearSampler(data, grid)
out [[[ 0, 0, 0, 0], [ 0, 3.5, 6.5, 0], [ 0, 1.25, 2.5, 0], [ 0, 0, 0, 0]]]
```
Example 2::

```python
## shift data horizontally by -1 pixel
data = array([[1, 4, 3, 6], [1, 8, 8, 9], [0, 4, 1, 5], [1, 0, 1, 3]])
warp_matrix = array([[1, 1, 1, 1], [1, 1, 1, 1], [1, 1, 1, 1], [1, 1, 1, 1], [0, 0, 0, 0], [0, 0, 0, 0], [0, 0, 0, 0]])
grid = GridGenerator(data=warp_matrix, transform_type='warp') out = BilinearSampler(data, grid)
out = [[4, 3, 6, 0], [8, 8, 9, 0], [4, 1, 5, 0], [0, 1, 3, 0]]
```

Defined in src/operator/bilinear_sampler.cc:L256

Value

out The result mx.symbol

---

**mx.symbol.BlockGrad**

*BlockGrad:* Stops gradient computation.

Description

Stops the accumulated gradient of the inputs from flowing through this operator in the backward direction. In other words, this operator prevents the contribution of its inputs to be taken into account for computing gradients.

Usage

`mx.symbol.BlockGrad(...)`

Arguments

<table>

<td>NDArray-or-Symbol The input array.</td>
</tr>
<tr>
<td>name</td>
<td>string, optional Name of the resulting symbol.</td>
</tr>
</tbody>
</table>

Details

Example::

```python
v1 = [1, 2] v2 = [0, 1] a = Variable('a') b = Variable('b') b_stop_grad = stop_gradient(3 * b) loss = MakeLoss(b_stop_grad + a)
executor = loss.simple_bind(ctx=cpu(), a=(1,2), b=(1,2)) executor.forward(is_train=True, a=v1, b=v2) executor.backward() executor.grad_arrays [0. 0. ] [1. 1. ]
```

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L325

Value

out The result mx.symbol
mx.symbol.broadcast_add

**broadcast_add**:
Returns element-wise sum of the input arrays with broadcasting.

### Description

'broadcast_plus' is an alias to the function 'broadcast_add'.

### Usage

```python
mx.symbol.broadcast_add(...)
```

### Arguments

- **lhs**: NDArray-or-Symbol
  First input to the function

- **rhs**: NDArray-or-Symbol
  Second input to the function

- **name**: string, optional
  Name of the resulting symbol.

### Details

**Example::**

```python
x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]
broadcast_add(x, y) = [[ 1., 1., 1.], [ 2., 2., 2.]]
broadcast_plus(x, y) = [[ 1., 1., 1.], [ 2., 2., 2.]]
```

Supported sparse operations:

```python
broadcast_add(csr, dense(1D)) = dense broadcast_add(dense(1D), csr) = dense
```

Defined in `src/operator/tensor/elemwise_binary_broadcast_op_basic.cc:L58`

### Value

```
out
```

The result mx.symbol
mx.symbol.broadcast_axes

broadcast_axes: Broadcasts the input array over particular axes.

Description

Broadcasting is allowed on axes with size 1, such as from ‘(2,1,3,1)’ to ‘(2,8,3,9)’. Elements will be duplicated on the broadcasted axes.

Usage

mx.symbol.broadcast_axes(...)

Arguments

data NDArray-or-Symbol The input
axis Shape(tuple), optional, default=[] The axes to perform the broadcasting.
size Shape(tuple), optional, default=[] Target sizes of the broadcasting axes.
name string, optional Name of the resulting symbol.

Details

‘broadcast_axes’ is an alias to the function ‘broadcast_axis’.

Example::

// given x of shape (1,2,1) x = [[1.], [2.]]

// broadcast x on axis 2 broadcast_axis(x, axis=2, size=3) = [[[1., 1., 1.], [2., 2., 2.]]] // broadcast x on axes 0 and 2 broadcast_axis(x, axis=(0,2), size=(2,3)) = [[[1., 1., 1.], [2., 2., 2.]], [[1., 1., 1.], [2., 2., 2.]]]

Defined in src/operator/tensor/broadcast_reduction_op_value.cc:L93

Value

out The result mx.symbol
**broadcast_axis**: Broadcasts the input array over particular axes.

**Description**

Broadcasting is allowed on axes with size 1, such as from `(2,1,3,1)` to `(2,8,3,9)`. Elements will be duplicated on the broadcasted axes.

**Usage**

```python
mx.symbol.broadcast_axis(...)
```

**Arguments**

- `data` : NDArray-or-Symbol The input
- `axis` : Shape(tuple), optional, default=[] The axes to perform the broadcasting.
- `size` : Shape(tuple), optional, default=[] Target sizes of the broadcasting axes.
- `name` : string, optional Name of the resulting symbol.

**Details**

'broadcast_axes' is an alias to the function 'broadcast_axis'.

**Example**::

```python
// given x of shape (1,2,1) x = [[[ 1.],  [ 2.]]]

// broadcast x on axis 2 broadcast_axis(x, axis=2, size=3) = [[[ 1.,  1.,  1.],  [ 2.,  2.,  2.]]] // broadcast

// broadcast x on axes 0 and 2 broadcast_axis(x, axis=(0,2), size=(2,3)) = [[[ 1.,  1.,  1.],  [ 2.,  2.,  2.]],  [[ 1.,  1.,  1.],  [ 2.,  2.,  2.]]]
```

Defined in `src/operator/tensor/broadcast_reduce_op_value.cc:L93`

**Value**

- `out` : The result `mx.symbol`
**mx.symbol.broadcast_div**

*broadcast_div:* Returns element-wise division of the input arrays with broadcasting.

**Description**

Example::

**Usage**

```
mx.symbol.broadcast_div(...)
```

**Arguments**

- `lhs` NDArray-or-Symbol First input to the function
- `rhs` NDArray-or-Symbol Second input to the function
- `name` string, optional Name of the resulting symbol.

**Details**

```
x = [[ 6., 6., 6.], [ 6., 6., 6.]]
y = [[ 2.], [ 3.]]
broadcast_div(x, y) = [[ 3., 3., 3.], [ 2., 2., 2.]]
```

Supported sparse operations:
```
broadcast_div(csr, dense(1D)) = csr
```

Defined in src/operator/tensor/elemwise_binary_broadcast_op_basic.cc:L187

**Value**

```
out The result mx.symbol
```

---

**mx.symbol.broadcast_equal**

*broadcast_equal:* Returns the result of element-wise **equal to** comparison operation with broadcasting.

**Description**

Example::

**Usage**

```
mx.symbol.broadcast_equal(...)
```
mx.symbol.broadcast_greater

Arguments

- **lhs** NDArray-or-Symbol First input to the function
- **rhs** NDArray-or-Symbol Second input to the function
- **name** string, optional Name of the resulting symbol.

Details

x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]
broadcast_equal(x, y) = [[ 0., 0., 0.], [ 1., 1., 1.]]
Defined in src/operator/tensor/elemwise_binary_broadcast_op_logic.cc:L46

Value

out The result mx.symbol

mx.symbol.broadcast_greater

broadcast_greater:Returns the result of element-wise **greater than** (>) comparison operation with broadcasting.

Description

Example::

Usage

mx.symbol.broadcast_greater(...)

Arguments

- **lhs** NDArray-or-Symbol First input to the function
- **rhs** NDArray-or-Symbol Second input to the function
- **name** string, optional Name of the resulting symbol.

Details

x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]
broadcast_greater(x, y) = [[ 1., 1., 1.], [ 0., 0., 0.]]
Defined in src/operator/tensor/elemwise_binary_broadcast_op_logic.cc:L82

Value

out The result mx.symbol
**mx.symbol.broadcast_greater_equal**

*broadcast_greater_equal:* Returns the result of element-wise **greater than or equal to** (>=) comparison operation with broadcasting.

### Description

Example::

### Usage

```python
mx.symbol.broadcast_greater_equal(...)```

### Arguments

- `lhs` : NDArray-or-Symbol First input to the function
- `rhs` : NDArray-or-Symbol Second input to the function
- `name` : string, optional Name of the resulting symbol.

### Details

```python
x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]
broadcast_greater_equal(x, y) = [[ 1., 1., 1.], [ 1., 1., 1.]]
```

Defined in `src/operator/tensor/elemwise_binary_broadcast_op_logic.cc:L100`

### Value

- `out` : The result `mx.symbol`

**mx.symbol.broadcast_hypot**

*broadcast_hypot:* Returns the hypotenuse of a right angled triangle, given its "legs" with broadcasting.

### Description

It is equivalent to doing :math:`\sqrt{x_1^2 + x_2^2}`.

### Usage

```python
mx.symbol.broadcast_hypot(...)```
mx.symbol.broadcast_lesser

Arguments

- **lhs**: NDArray-or-Symbol First input to the function
- **rhs**: NDArray-or-Symbol Second input to the function
- **name**: string, optional Name of the resulting symbol.

Details

Example::

```python
x = [[ 3., 3., 3.]]
y = [[ 4.], [ 4.]]
broadcast_hypot(x, y) = [[ 5., 5., 5.], [ 5., 5., 5.]]
z = [[ 0.], [ 4.]]
broadcast_hypot(x, z) = [[ 3., 3., 3.], [ 5., 5., 5.]]
```

Defined in src/operator/tensor/elemwise_binary_broadcast_op_extended.cc:L158

Value

- **out**: The result mx.symbol

mx.symbol.broadcast_lesser

broadcast_lesser:Returns the result of element-wise **lesser than** (\(<\)) comparison operation with broadcasting.

Description

Example::

Usage

```python
mx.symbol.broadcast_lesser(...)
```

Arguments

- **lhs**: NDArray-or-Symbol First input to the function
- **rhs**: NDArray-or-Symbol Second input to the function
- **name**: string, optional Name of the resulting symbol.

Details

```
x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]
broadcast_lesser(x, y) = [[ 0., 0., 0.], [ 0., 0., 0.]]
```

Defined in src/operator/tensor/elemwise_binary_broadcast_op_logic.cc:L118
**mx.symbol.broadcast_lesser_equal**

*broadcast_lesser_equal*: Returns the result of element-wise "less than or equal to" (\(\leq\)) comparison operation with broadcasting.

### Description

Example::

```python
x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]
broadcast_lesser_equal(x, y) = [[ 0., 0., 0.], [ 1., 1., 1.]]
```

Defined in src/operator/tensor/elemwise_binary_broadcast_op_logic.cc:L136

### Arguments

- **lhs**: NDArray-or-Symbol
  First input to the function

- **rhs**: NDArray-or-Symbol
  Second input to the function

- **name**: string, optional
  Name of the resulting symbol.

### Details

```python
x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]
broadcast_lesser_equal(x, y) = [[ 0., 0., 0.], [ 1., 1., 1.]]
```

Defined in src/operator/tensor/elemwise_binary_broadcast_op_logic.cc:L136

### Value

- **out**: The result mx.symbol
mx.symbol.broadcast_like

broadcast_like: Broadcasts lhs to have the same shape as rhs.

Description

Broadcasting is a mechanism that allows NDArrays to perform arithmetic operations with arrays of different shapes efficiently without creating multiple copies of arrays. Also see, ‘Broadcasting <https://docs.scipy.org/doc/numpy/user/basics.broadcasting.html>’ for more explanation.

Usage

mx.symbol.broadcast_like(...)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lhs</td>
<td>NDArray-or-Symbol First input.</td>
</tr>
<tr>
<td>rhs</td>
<td>NDArray-or-Symbol Second input.</td>
</tr>
<tr>
<td>lhs.axes</td>
<td>Shape or None, optional, default=None Axes to perform broadcast on in the first input array</td>
</tr>
<tr>
<td>rhs.axes</td>
<td>Shape or None, optional, default=None Axes to copy from the second input array</td>
</tr>
<tr>
<td>name</td>
<td>string, optional Name of the resulting symbol.</td>
</tr>
</tbody>
</table>

Details

Broadcasting is allowed on axes with size 1, such as from `(2,1,3,1)` to `(2,8,3,9)`. Elements will be duplicated on the broadcasted axes.

For example:

```
broadcast_like([[1,2,3]], [[5,6,7],[7,8,9]]) = [[ 1., 2., 3.], [ 1., 2., 3.]]
broadcast_like([9], [1,2,3,4,5], lhs_axes=(0,), rhs_axes=(-1,)) = [9,9,9,9,9]
```

Defined in src/operator/tensor/broadcast_reduce_op_value.cc:L179

Value

out The result mx.symbol
**mx.symbol.broadcast_logical_and**

*broadcast_logical_and:* Returns the result of element-wise **logical and** with broadcasting.

**Description**

Example::

**Usage**

```
mx.symbol.broadcast_logical_and(...)
```

**Arguments**

- **lhs**: NDArray-or-Symbol First input to the function
- **rhs**: NDArray-or-Symbol Second input to the function
- **name**: string, optional Name of the resulting symbol.

**Details**

```
x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0., 1.]]
broadcast_logical_and(x, y) = [[ 0., 0., 1.], [ 1., 1., 1.]]
```

Defined in src/operator/tensor/elemwise_binary_broadcast_op_logic.cc:L154

**Value**

```
out The result mx.symbol
```

---

**mx.symbol.broadcast_logical_or**

*broadcast_logical_or:* Returns the result of element-wise **logical or** with broadcasting.

**Description**

Example::

**Usage**

```
mx.symbol.broadcast_logical_or(...)
```
mx.symbol.broadcast_logical_xor

Arguments

1hs NDArray-or-Symbol First input to the function
rhs NDArray-or-Symbol Second input to the function
name string, optional Name of the resulting symbol.

Details

\[ x = \begin{bmatrix} 1., 1., 0. \\ 1., 1., 0. \end{bmatrix} \]
\[ y = \begin{bmatrix} 1. \\ 0. \end{bmatrix} \]
\[ \text{broadcast\_logical\_or}(x, y) = \begin{bmatrix} 1., 1., 1. \\ 1., 1., 0. \end{bmatrix} \]
Defined in src/operator/tensor/elemwise_binary_broadcast_op_logic.cc:L172

Value

out The result mx.symbol

mx.symbol.broadcast_logical_xor

broadcast_logical_xor:Returns the result of element-wise **logical xor** with broadcasting.

Description

Example::

Usage

mx.symbol.broadcast_logical_xor(...)
mx.symbol.broadcast_maximum

Returns element-wise maximum of the input arrays with broadcasting.

**Description**

This function compares two input arrays and returns a new array having the element-wise maxima.

**Usage**

mx.symbol.broadcast_maximum(...)

**Arguments**

- lhs: NDArray-or-Symbol, First input to the function
- rhs: NDArray-or-Symbol, Second input to the function
- name: string, optional, Name of the resulting symbol.

**Details**

Example::

x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]
broadcast_maximum(x, y) = [[ 1., 1., 1.], [ 1., 1., 1.]]

Defined in src/operator/tensor/elemwise_binary_broadcast_op_extended.cc:L81

**Value**

out, The result mx.symbol

mx.symbol.broadcast_minimum

Returns element-wise minimum of the input arrays with broadcasting.

**Description**

This function compares two input arrays and returns a new array having the element-wise minima.

**Usage**

mx.symbol.broadcast_minimum(...)

**Arguments**

- lhs: NDArray-or-Symbol, First input to the function
- rhs: NDArray-or-Symbol, Second input to the function
- name: string, optional, Name of the resulting symbol.

**Details**

Example::

x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]
broadcast_minimum(x, y) = [[ 0., 1., 1.], [ 1., 1., 1.]]

Defined in src/operator/tensor/elemwise_binary_broadcast_op_extended.cc:L81

**Value**

out, The result mx.symbol
mx.symbol.broadcast_minus

**Arguments**

- **lhs**: NDArray-or-Symbol First input to the function
- **rhs**: NDArray-or-Symbol Second input to the function
- **name**: string, optional Name of the resulting symbol.

**Details**

**Example**:

```python
x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]
broadcast_maximum(x, y) = [[ 0., 0., 0.], [ 1., 1., 1.]]
```

Defined in `src/operator/tensor/elemwise_binary_broadcast_op_extended.cc:L117`

**Value**

```python
out The result mx.symbol
```

---

**Description**

‘broadcast_minus’ is an alias to the function ‘broadcast_sub’.

**Usage**

```python
mx.symbol.broadcast_minus(...)```

**Arguments**

- **lhs**: NDArray-or-Symbol First input to the function
- **rhs**: NDArray-or-Symbol Second input to the function
- **name**: string, optional Name of the resulting symbol.

**Details**

**Example**:

```python
x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]
broadcast_sub(x, y) = [[ 1., 1., 1.], [ 0., 0., 0.]]
broadcast_minus(x, y) = [[ 1., 1., 1.], [ 0., 0., 0.]]
```
Supported sparse operations:
broadcast_sub/minus(csr, dense(1D)) = dense broadcast_sub/minus(dense(1D), csr) = dense
Defined in src/operator/tensor/elemwise_binary_broadcast_op_basic.cc:L106

Value
out The result mx.symbol

mx.symbol.broadcast_mod

broadcast_mod:Returns element-wise modulo of the input arrays with broadcasting.

Description
Example::

Usage
mx.symbol.broadcast_mod(...)

Arguments
lhs NDArray-or-Symbol First input to the function
rhs NDArray-or-Symbol Second input to the function
name string, optional Name of the resulting symbol.

Details
x = [[ 8., 8., 8.], [ 8., 8., 8.]]
y = [[ 2.], [ 3.]]
broadcast_mod(x, y) = [[ 0., 0., 0.], [ 2., 2., 2.]]
Defined in src/operator/tensor/elemwise_binary_broadcast_op_basic.cc:L222

Value
out The result mx.symbol
mx.symbol.broadcast_mul

**broadcast_mul:** Returns element-wise product of the input arrays with broadcasting.

### Description

Example::

### Usage

```python
mx.symbol.broadcast_mul(…)
```

### Arguments

- **lhs**: NDArray-or-Symbol First input to the function
- **rhs**: NDArray-or-Symbol Second input to the function
- **name**: string, optional Name of the resulting symbol.

### Details

```python
x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]
broadcast_mul(x, y) = [[ 0., 0., 0.], [ 1., 1., 1.]]
```

Supported sparse operations:
- `broadcast_mul(csr, dense(1D)) = csr`

Defined in src/operator/tensor/elemwise_binary_broadcast_op_basic.cc:L146

### Value

- **out**: The result `mx.symbol`

mx.symbol.broadcast_not_equal

**broadcast_not_equal:** Returns the result of element-wise **not equal** to**!=** comparison operation with broadcasting.

### Description

Example::

### Usage

```python
mx.symbol.broadcast_not_equal(…)
```
**Arguments**

- `lhs` NDArray-or-Symbol First input to the function
- `rhs` NDArray-or-Symbol Second input to the function
- `name` string, optional Name of the resulting symbol.

**Details**

```plaintext
x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]
broadcast_not_equal(x, y) = [[ 1., 1., 1.], [ 0., 0., 0.]]
Defined in src/operator/tensor/elementwise_binary_broadcast_op_logic.cc:L64
```

**Value**

- `out` The result mx.symbol

---

**Description**

‘broadcast_plus’ is an alias to the function ‘broadcast_add’.

**Usage**

```python
mx.symbol.broadcast_plus(...)
```

**Arguments**

- `lhs` NDArray-or-Symbol First input to the function
- `rhs` NDArray-or-Symbol Second input to the function
- `name` string, optional Name of the resulting symbol.

**Details**

Example::

```plaintext
x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]
broadcast_add(x, y) = [[ 1., 1., 1.], [ 2., 2., 2.]]
broadcast_plus(x, y) = [[ 1., 1., 1.], [ 2., 2., 2.]]
```

Supported sparse operations:

```plaintext
broadcast_add(csr, dense(1D)) = dense broadcast_add(dense(1D), csr) = dense
```

Defined in src/operator/tensor/elementwise_binary_broadcast_op_basic.cc:L58
Value
out The result mx.symbol

Description

Example::

Usage
mx.symbol.broadcast_power(...)

Arguments

lhs NDArray-or-Symbol First input to the function
rhs NDArray-or-Symbol Second input to the function
name string, optional Name of the resulting symbol.

Details

x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]

broadcast_power(x, y) = [[ 2., 2., 2.], [ 4., 4., 4.]]

Defined in src/operator/tensor/elementwise_binary_broadcast_op_extended.cc:L45

Value
out The result mx.symbol
**mx.symbol.broadcast_sub**

*broadcast_sub*: Returns element-wise difference of the input arrays with broadcasting.

**Description**

'broadcast_minus' is an alias to the function 'broadcast_sub'.

**Usage**

mx.symbol.broadcast_sub(...)

**Arguments**

- **lhs**: NDArray-or-Symbol First input to the function
- **rhs**: NDArray-or-Symbol Second input to the function
- **name**: string, optional Name of the resulting symbol.

**Details**

Example::

x = [[ 1., 1., 1.], [ 1., 1., 1.]]
y = [[ 0.], [ 1.]]
broadcast_sub(x, y) = [[ 1., 1., 1.], [ 0., 0., 0.]]
broadcast_minus(x, y) = [[ 1., 1., 1.], [ 0., 0., 0.]]

Supported sparse operations:

broadcast_sub/minus(csr, dense(1D)) = dense broadcast_sub/minus(dense(1D), csr) = dense

Defined in src/operator/tensor/elemwise_binary_broadcast_op_basic.cc:L106

**Value**

out The result mx.symbol
mx.symbol.broadcast_to

broadcast_to: Broadcasts the input array to a new shape.

Description

Broadcasting is a mechanism that allows NDArrays to perform arithmetic operations with arrays of different shapes efficiently without creating multiple copies of arrays. Also see, ‘Broadcasting <https://docs.scipy.org/doc/numpy/user/basics.broadcasting.html>’ for more explanation.

Usage

mx.symbol.broadcast_to(...)

Arguments

data: NDArray-or-Symbol
The input

shape: Shape(tuple), optional, default=[]
The shape of the desired array. We can set the dim to zero if it's same as the original. E.g ‘A = broadcast_to(B, shape=(10, 0, 0))’ has the same meaning as ‘A = broadcast_axis(B, axis=0, size=10)’.

name: string, optional
Name of the resulting symbol.

Details

Broadcasting is allowed on axes with size 1, such as from ‘(2,1,3,1)’ to ‘(2,8,3,9)’. Elements will be duplicated on the broadcasted axes.

For example:

```
broadcast_to([[1,2,3]], shape=(2,3)) = [[ 1., 2., 3.], [ 1., 2., 3.]]
```

The dimension which you do not want to change can also be kept as ‘0’ which means copy the original value. So with ‘shape=(2,0)’, we will obtain the same result as in the above example.

Defined in src/operator/tensor/broadcast_reduce_op_value.cc:L117

Value

out: The result mx.symbol
mx.symbol.cast

Cast:Casts all elements of the input to a new type.

Description

.. note:: “Cast” is deprecated. Use “cast” instead.

Usage

mx.symbol.cast(...)

Arguments

data: NDArray-or-Symbol The input.
dtype: 'bfloat16', 'bool', 'float16', 'float32', 'float64', 'int32', 'int64', 'int8', 'uint8',
required Output data type.
name: string, optional Name of the resulting symbol.

Details

Example::

cast([0.9, 1.3], dtype='int32') = [0, 1] cast([1e20, 11.1], dtype='float16') = [inf, 11.09375] cast([300, 11.1, 10.9, -1, -3], dtype='uint8') = [44, 11, 10, 255, 253]

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L664

Value

out The result mx.symbol

mx.symbol.cast

cast:Casts all elements of the input to a new type.

Description

.. note:: “Cast” is deprecated. Use “cast” instead.

Usage

mx.symbol.cast(...)

Arguments

data: NDArray-or-Symbol The input.
dtype: 'bfloat16', 'bool', 'float16', 'float32', 'float64', 'int32', 'int64', 'int8', 'uint8',
required Output data type.
name: string, optional Name of the resulting symbol.
mx.symbol.cast_storage

Details

Example:

```
cast([0.9, 1.3], dtype='int32') = [0, 1] 
cast([1e20, 11.1], dtype='float16') = [inf, 11.09375] 
cast([300, 11.2, 10.9, -1, -3], dtype='uint8') = [44, 11, 10, 255, 253]
```

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L664

Value

```
out The result mx.symbol
```

Description

When an NDArray with default storage type is cast to csr or row_sparse storage, the result is compact, which means:

Usage

```
mx.symbol.cast_storage(...)
```

Arguments

```
data NDArray-or-Symbol The input.
stype 'csr', 'default', 'row_sparse', required Output storage type.
name string, optional Name of the resulting symbol.
```

Details

- for csr, zero values will not be retained - for row_sparse, row slices of all zeros will not be retained

The storage type of “cast_storage“ output depends on stype parameter:

```
cast_storage(csr, 'default') = default
cast_storage(row_sparse, 'default') = default
cast_storage(default, 'csr') = csr
cast_storage(default, 'row_sparse') = row_sparse
cast_storage(csr, 'csr') = csr
cast_storage(row_sparse, 'row_sparse') = row_sparse
```

Example::

```
dense = [[ 0., 1., 0.], [ 2., 0., 3.], [ 0., 0., 0.], [ 0., 0., 0.]]

# cast to row_sparse storage type 

rsp = cast_storage(dense, 'row_sparse') 

rsp.indices = [0, 1] 

rsp.values = [[sqrt(0.), 1., 0.], [ 2., 0., 3.]]

# cast to csr storage type 

csr = cast_storage(dense, 'csr')

csr.indices = [1, 0, 2] 

csr.values = [ 1., 2., 3.] 

csr.indptr = [0, 1, 3, 3, 3]
```

Defined in src/operator/tensor/cast_storage.cc:L71
mx.symbol.ceil

cell: Returns element-wise ceiling of the input.

Value

out The result mx.symbol

mx.symbol.cbrt

cbrt: Returns element-wise cube-root value of the input.

Description

.. math:: cbrt(x) = \sqrt[3]{x}

Usage

mx.symbol.cbrt(...)  

Arguments

data NDArray-or-Symbol The input array.
name string, optional Name of the resulting symbol.

Details

Example::

cbrt([1, 8, -125]) = [1, 2, -5]

The storage type of "cbrt" output depends upon the input storage type:

- cbrt(default) = default  
- cbrt(row_sparse) = row_sparse  
- cbrt(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_pow.cc:L270

Value

out The result mx.symbol

mx.symbol.ceil

cell: Returns element-wise ceiling of the input.

Description

The ceil of the scalar x is the smallest integer i, such that i >= x.

Usage

mx.symbol.ceil(...)

Arguments

data NDArray-or-Symbol The input array.
nama string, optional Name of the resulting symbol.

Details

Example::

cell([-2.1, -1.9, 1.5, 1.9, 2.1]) = [-2., -1., 2., 2., 3.]

The storage type of “cell” output depends upon the input storage type:
- cell(default) = default - cell(row_sparse) = row_sparse - cell(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L817

Value

out The result mx.symbol

Description

Given an input array of shape “(d0, d1)” and indices of shape “(i0,)”, the result will be an output array of shape “(i0,)” with:

Usage

mx.symbol.choose_element_0index(...) 

Arguments 

data NDArray-or-Symbol The input array 
index NDArray-or-Symbol The index array 
axis int or None, optional, default=-1 int or None. The axis to picking the elements. Negative values means indexing from right to left. If is ‘None’, the elements in the index w.r.t the flattened input will be picked. 
keepdims boolean, optional, default=0 If true, the axis where we pick the elements is left in the result as dimension with size one. 
mode 'clip', 'wrap',optional, default='clip' Specify how out-of-bound indices behave. Default is "clip". "clip" means clip to the range. So, if all indices mentioned are too large, they are replaced by the index that addresses the last element along an axis. "wrap" means to wrap around. 
nama string, optional Name of the resulting symbol.
Details

output[i] = input[i, indices[i]]

By default, if any index mentioned is too large, it is replaced by the index that addresses the last element along an axis (the ‘clip’ mode).

This function supports n-dimensional input and (n-1)-dimensional indices arrays.

Examples::

x = [[ 1., 2.], [ 3., 4.], [ 5., 6.]]
// picks elements with specified indices along axis 0 pick(x, y=[0,1], 0) = [ 1., 4.]
// picks elements with specified indices along axis 1 pick(x, y=[0,1,0], 1) = [ 1., 4., 5.]
// picks elements with specified indices along axis 1 using ‘wrap’ mode // to place indicies that would normally be out of bounds pick(x, y=[2,-1,-2], 1, mode='wrap') = [ 1., 4., 5.]
y = [[ 1.], [ 0.], [ 2.]]
// picks elements with specified indices along axis 1 and dims are maintained pick(x, y, 1, keep-dims=True) = [[ 2.], [ 3.], [ 6.]]

Defined in src/operator/tensor/broadcast_reduce_op_index.cc:L151

Value

out The result mx.symbol

mx.symbol.clip

clip:Clips (limits) the values in an array. Given an interval, values outside the interval are clipped to the interval edges. Clipping “x” between ‘a_min’ and ‘a_max’ would be:: .. math:: clip(x, a_min, a_max) = \max(\min(x, a_max), a_min))

Example:: x = [0, 1, 2, 3, 4, 5, 6, 7, 8, 9] clip(x,1,8) = [ 1., 1., 2., 3., 4., 5., 6., 7., 8., 8.]

The storage type of “clip” output depends on storage types of inputs and the a_min, a_max\ parameter values:
- clip(default) = default - clip(row_sparse, a_min <= 0, a_max >= 0) = row_sparse - clip(csr, a_min <= 0, a_max >= 0) = csr - clip(row_sparse, a_min < 0, a_max < 0) = default - clip(csr, a_min < 0, a_max < 0) = csr - clip(csr, a_min > 0, a_max > 0) = default - clip(csr, a_min < 0, a_max < 0) = csr - clip(csr, a_min > 0, a_max > 0) = csr

Description

Defined in src/operator/tensor/matrix_op.cc:L677

Usage

mx.symbol.clip(...)
mx.symbol.col2im

Arguments

- **data**: NDArray-or-Symbol Input array.
- **a.min**: float, required Minimum value
- **a.max**: float, required Maximum value
- **name**: string, optional Name of the resulting symbol.

Value

- **out**: The result mx.symbol

mx.symbol.col2im

col2im:Combining the output column matrix of im2col back to image array.

Description

Like :class:`~mxnet.ndarray.im2col`, this operator is also used in the vanilla convolution implementation. Despite the name, col2im is not the reverse operation of im2col. Since there may be overlaps between neighbouring sliding blocks, the column elements cannot be directly put back into image. Instead, they are accumulated (i.e., summed) in the input image just like the gradient computation, so col2im is the gradient of im2col and vice versa.

Usage

mx.symbol.col2im(...)

Arguments

- **data**: NDArray-or-Symbol Input array to combine sliding blocks.
- **output.size**: Shape(tuple), required The spatial dimension of image array: (w,), (h, w) or (d, h, w).
- **kernel**: Shape(tuple), required Sliding kernel size: (w,), (h, w) or (d, h, w).
- **stride**: Shape(tuple), optional, default=[] The stride between adjacent sliding blocks in spatial dimension: (w,), (h, w) or (d, h, w). Defaults to 1 for each dimension.
- **dilate**: Shape(tuple), optional, default=[] The spacing between adjacent kernel points: (w,), (h, w) or (d, h, w). Defaults to 1 for each dimension.
- **pad**: Shape(tuple), optional, default=[] The zero-value padding size on both sides of spatial dimension: (w,), (h, w) or (d, h, w). Defaults to no padding.
- **name**: string, optional Name of the resulting symbol.
**mx.symbol.Concat**

**Details**

Using the notation in im2col, given an input column array of shape :math:`(N, C \times \prod{textkernel}, W)`; this operator accumulates the column elements into output array of shape :math:`(N, C, \text{output_size}[0], \text{output_size}[1], \ldots)`. Only 1-D, 2-D and 3-D of spatial dimension is supported in this operator.

Defined in src/operator/nn/im2col.cc:L182

**Value**

out The result mx.symbol

---

**mx.symbol.Concat**  
Perform an feature concat on channel dim (dim 1) over all the inputs.

**Description**

Perform an feature concat on channel dim (dim 1) over all the inputs.

**Usage**

mx.symbol.Concat(data, num.args, dim = NULL, name = NULL)

**Arguments**

- **data**  
  list, required  
  List of tensors to concatenate

- **num.args**  
  int, required  
  Number of inputs to be concated.

- **dim**  
  int, optional, default=’1’  
  the dimension to be concated.

- **name**  
  string, optional  
  Name of the resulting symbol.

**Value**

out The result mx.symbol
mx.symbol.concat

Perform an feature concat on channel dim (dim 1) over all the inputs.

Description

Perform an feature concat on channel dim (dim 1) over all the inputs.

Usage

mx.symbol.concat(data, num.args, dim = NULL, name = NULL)

Arguments

data list, required List of tensors to concatenate
num.args int, required Number of inputs to be concated.
dim int, optional, default='1' the dimension to be concated.
name string, optional Name of the resulting symbol.

Value

out The result mx.symbol

mx.symbol.Convolution

Convolution: Compute *N*-D convolution on *(N+2)*-D input.

Description

In the 2-D convolution, given input data with shape *(batch_size, channel, height, width)*, the output is computed by

Usage

mx.symbol.Convolution(...)

Arguments

data NDArray-or-Symbol Input data to the ConvolutionOp.
weight NDArray-or-Symbol Weight matrix.
bias NDArray-or-Symbol Bias parameter.
kernel Shape(tuple), required Convolution kernel size: (w,), (h, w) or (d, h, w)
stride Shape(tuple), optional, default=[] Convolution stride: (w,), (h, w) or (d, h, w). Defaults to 1 for each dimension.
dilate Shape(tuple), optional, default=[] Convolution dilate: (w,), (h, w) or (d, h, w). Defaults to 1 for each dimension.
mx.symbol.Convolution

pad Shape(tuple), optional, default=[] Zero pad for convolution: (w,), (h, w) or (d, h, w). Defaults to no padding.

num.filter int (non-negative), required Convolution filter(channel) number

num.group int (non-negative), optional, default=1 Number of group partitions.

workspace long (non-negative), optional, default=1024 Maximum temporary workspace allowed (MB) in convolution. This parameter has two usages. When CUDNN is not used, it determines the effective batch size of the convolution kernel. When CUDNN is used, it controls the maximum temporary storage used for tuning the best CUDNN kernel when ‘limited_workspace’ strategy is used.

no.bias boolean, optional, default=0 Whether to disable bias parameter.

cudnn.off boolean, optional, default=0 Turn off cudnn for this layer.

layout None, ‘NCDHW’, ‘NCHW’, ‘NCW’, ‘NDHWC’, ‘NHWC’, optional, default=’None’ Set layout for input, output and weight. Empty for default layout: NCW for 1d, NCHW for 2d and NCDHW for 3d. NHWC and NDHWC are only supported on GPU.

name string, optional Name of the resulting symbol.

Details

.. math::
   \text{out}[n,i,:,\ldots] = \text{bias}[i] + \sum_{j=0}^{\text{channel}} \text{data}[n,j,:,\ldots] \star \text{weight}[i,j,:,\ldots]

where :math:`\star` is the 2-D cross-correlation operator.

For general 2-D convolution, the shapes are

- **data**: *(batch_size, channel, height, width)*
- **weight**: *(num_filter, channel, kernel[0], kernel[1])*
- **bias**: *(num_filter,)*
- **out**: *(batch_size, num_filter, out_height, out_width)*

Define::

f(x,k,p,s,d) = floor((x+2*p-d*(k-1)-1)/s)+1

then we have::

out_height=f(height, kernel[0], pad[0], stride[0], dilate[0])
out_width=f(width, kernel[1], pad[1], stride[1], dilate[1])

If “no_bias” is set to be true, then the “bias” term is ignored.

The default data “layout” is *NCHW*, namely *(batch_size, channel, height, width)*. We can choose other layouts such as *NWC*.

If “num_group” is larger than 1, denoted by *g*, then split the input “data” evenly into *g* parts along the channel axis, and also evenly split “weight” along the first dimension. Next compute the convolution on the *i*-th part of the data with the *i*-th weight part. The output is obtained by concatenating all the *g* results.

1-D convolution does not have *height* dimension but only *width* in space.

- **data**: *(batch_size, channel, width)*
- **weight**: *(num_filter, channel, kernel[0])*  
- **bias**: *(num_filter,)* 
- **out**: *(batch_size, num_filter, out_width)*.
3-D convolution adds an additional *depth* dimension besides *height* and *width*. The shapes are
- **data**: *(batch_size, channel, depth, height, width)* - **weight**: *(num_filter, channel, kernel[0], kernel[1], kernel[2])* - **bias**: *(num_filter,)* - **out**: *(batch_size, num_filter, out_depth, out_height, out_width)*.

Both "weight" and "bias" are learnable parameters.

There are other options to tune the performance.
- **cudnn_tune**: enable this option leads to higher startup time but may give faster speed. Options are
  - **off**: no tuning - **limited_workspace**:run test and pick the fastest algorithm that doesn’t exceed workspace limit. - **fastest**: pick the fastest algorithm and ignore workspace limit. - **None** (default): the behavior is determined by environment variable “MXNET_CUDNN_AUTOTUNE_DEFAULT”. 0 for off, 1 for limited workspace (default), 2 for fastest.
- **workspace**: A large number leads to more (GPU) memory usage but may improve the performance.

Defined in src/operator/nn/convolution.cc:L476

### Value

out The result mx.symbol

mx.symbol.Convolution_v1

*Convolution_v1:* This operator is DEPRECATED. Apply convolution to input then add a bias.

### Description

Convolution_v1:*This operator is DEPRECATED. Apply convolution to input then add a bias.

### Usage

mx.symbol.Convolution_v1(...)

### Arguments

**mx.symbol.Correlation**  
*Correlation: Applies correlation to inputs.*

**Description**

The correlation layer performs multiplicative patch comparisons between two feature maps.

**Usage**

`mx.symbol.Correlation(...)`

**Arguments**

- `data1` NDArray-or-Symbol Input data1 to the correlation.
- `data2` NDArray-or-Symbol Input data2 to the correlation.
- `kernel.size` int (non-negative), optional, default=1 kernel size for Correlation must be an odd number
**max.displacement**  
int (non-negative), optional, default=1 Max displacement of Correlation

**stride1**  
int (non-negative), optional, default=1 stride1 quantize data1 globally

**stride2**  
int (non-negative), optional, default=1 stride2 quantize data2 within the neighborhood centered around data1

**pad.size**  
int (non-negative), optional, default=0 pad for Correlation

**is.multiply**  
boolean, optional, default=1 operation type is either multiplication or subduction

**name**  
string, optional Name of the resulting symbol.

### Details

Given two multi-channel feature maps :math:`f_1, f_2`, with :math:`w`, :math:`h`, and :math:`c` being their width, height, and number of channels, the correlation layer lets the network compare each patch from :math:`f_1` with each patch from :math:`f_2`.

For now we consider only a single comparison of two patches. The `correlation` of two patches centered at :math:`x_1` in the first map and :math:`x_2` in the second map is then defined as:

\[
c(x_1, x_2) = \sum_{o \in [-k,k] \times [-k,k]} <f_1(x_1 + o), f_2(x_2 + o)>
\]

for a square patch of size :math:`K:=2k+1`.

Note that the equation above is identical to one step of a convolution in neural networks, but instead of convolving data with a filter, it convolves data with other data. For this reason, it has no training weights.

Computing :math:`c(x_1, x_2)` involves :math:`c * K^2` multiplications. Comparing all patch combinations involves :math:`w^2 * h^2` such computations.

Given a maximum displacement :math:`d`, for each location :math:`x_1` it computes correlations :math:`c(x_1, x_2)` only in a neighborhood of size :math:`D:=2d+1`, by limiting the range of :math:`x_2`. We use strides :math:`s_1, s_2`, to quantize :math:`x_1` globally and to quantize :math:`x_2` within the neighborhood centered around :math:`x_1`.

The final output is defined by the following expression:

\[
out[n, q, i, j] = c(x_{i, j}, x_q)
\]

Defined in src/operator/correlation.cc:L198

### Value

out The result mx.symbol
**mx.symbol.cos**

cos: Computes the element-wise cosine of the input array.

**Description**

The input should be in radians (\(2\pi\) rad equals 360 degrees).

**Usage**

```python
mx.symbol.cos(...)```

**Arguments**

- `data` NDArray-or-Symbol: The input array.
- `name` string, optional: Name of the resulting symbol.

**Details**

.. math:: 
   \cos([0, \pi/4, \pi/2]) = [1, 0.707, 0]

The storage type of “cos” output is always dense

Defined in `src/operator/tensor/elemwise_unary_op_trig.cc:L90`

**Value**

- `out` The result mx.symbol

**mx.symbol.cosh**

cosh: Returns the hyperbolic cosine of the input array, computed element-wise.

**Description**

.. math:: 
   \cosh(x) = 0.5\times(\exp(x) + \exp(-x))

**Usage**

```python
mx.symbol.cosh(...)```

**Arguments**

- `data` NDArray-or-Symbol: The input array.
- `name` string, optional: Name of the resulting symbol.
mx.symbol.Crop

Details

The storage type of “cosh” output is always dense
Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L409

Value

out The result mx.symbol

mx.symbol.Crop

Description

.. note:: ‘Crop’ is deprecated. Use ‘slice’ instead.

Usage

mx.symbol.Crop(...)

Arguments

data Symbol or Symbol[] Tensor or List of Tensors, the second input will be used as
crop_like shape reference
num.args int, required Number of inputs for crop, if equals one, then we will use the
h_w for crop height and width, else if equals two, then we will use the height and
width of the second input symbol, we name crop_like here
offset Shape(tuple), optional, default=[0,0] crop offset coordinate: (y, x)
h.w Shape(tuple), optional, default=[0,0] crop height and width: (h, w)
center.crop boolean, optional, default=0 If set to true, then it will use be the center_crop, or
it will crop using the shape of crop_like
name string, optional Name of the resulting symbol.

Details

Crop the 2nd and 3rd dim of input data, with the corresponding size of h_w or with width and height
of the second input symbol, i.e., with one input, we need h_w to specify the crop height and width,
otherwise the second input symbol’s size will be used
Defined in src/operator/crop.cc:L50

Value

out The result mx.symbol
**Description**

Defined in src/operator/tensor/matrix_op.cc:L482

**Usage**

```python
mx.symbol.crop(...)
```

**Arguments**

- `data` (NDArray-or-Symbol): Source input.
- `begin` (Shape(tuple)): Required starting indices for the slice operation, supports negative indices.
- `end` (Shape(tuple)): Required ending indices for the slice operation, supports negative indices.
- `step` (Shape(tuple), optional, default=[]): Step for the slice operation, supports negative values.
- `name` (string, optional): Name of the resulting symbol.

**Value**

- `out` (The result mx.symbol)
mx.symbol.CTCLoss

CTCLoss: Connectionist Temporal Classification Loss.

Description

.. note:: The existing alias "contrib_CTCLoss" is deprecated.

Usage

mx.symbol.CTCLoss(...)

Arguments

data NDArray-or-Symbol Input ndarray

label NDArray-or-Symbol Ground-truth labels for the loss.

data.lengths NDArray-or-Symbol Lengths of data for each of the samples. Only required when use_data_lengths is true.

label.lengths NDArray-or-Symbol Lengths of labels for each of the samples. Only required when use_label_lengths is true.

use.data.lengths boolean, optional, default=0 Whether the data lengths are decided by 'data_lengths'. If false, the lengths are equal to the max sequence length.

use.label.lengths boolean, optional, default=0 Whether the label lengths are decided by 'label_lengths', or derived from 'padding_mask'. If false, the lengths are derived from the first occurrence of the value of 'padding_mask'. The value of 'padding_mask' is "0" when first CTC label is reserved for blank, and "-1" when last label is reserved for blank. See 'blank_label'.

blank.label 'first', 'last',optional, default='first' Set the label that is reserved for blank label. If "first", 0-th label is reserved, and label values for tokens in the vocabulary are between "1" and "alphabet_size-1", and the padding mask is "-1". If "last", last label value "alphabet_size-1" is reserved for blank label instead, and label values for tokens in the vocabulary are between "0" and "alphabet_size-2", and the padding mask is "0".

name string, optional Name of the resulting symbol.

Details

The shapes of the inputs and outputs:

- **data**: '(sequence_length, batch_size, alphabet_size)' - **label**: '(batch_size, label_sequence_length)' - **out**: '(batch_size)'

The 'data' tensor consists of sequences of activation vectors (without applying softmax), with i-th channel in the last dimension corresponding to i-th label for i between 0 and alphabet_size-1 (i.e always 0-indexed). Alphabet size should include one additional value reserved for blank label.
When ‘blank_label’ is “first”, the “0”-th channel is be reserved for activation of blank label, otherwise if it is "last", "(alphabet_size-1)"-th channel should be reserved for blank label.

“label” is an index matrix of integers. When ‘blank_label’ is “first", the value 0 is then reserved for blank label, and should not be passed in this matrix. Otherwise, when ‘blank_label’ is "last", the value ‘(alphabet_size-1)’ is reserved for blank label.

If a sequence of labels is shorter than *label_sequence_length*, use the special padding value at the end of the sequence to conform it to the correct length. The padding value is ‘0’ when ‘blank_label’ is “first”, and ‘-1’ otherwise.

For example, suppose the vocabulary is ‘[a, b, c]|, and in one batch we have three sequences ‘ba’, ‘cbb’, and ’abac’. When ‘blank_label’ is “first", we can index the labels as ‘a’: 1, ’b’: 2, ’c’: 3, and we reserve the 0-th channel for blank label in data tensor. The resulting ‘label’ tensor should be padded to be:

$$[[2, 1, 0, 0], [3, 2, 2, 0], [1, 2, 1, 3]]$$

When ‘blank_label’ is “last", we can index the labels as ‘a’: 0, ’b’: 1, ’c’: 2, and we reserve the channel index 3 for blank label in data tensor. The resulting ‘label’ tensor should be padded to be:

$$[[1, 0, -1, -1], [2, 1, 1, -1], [0, 1, 0, 2]]$$

“out” is a list of CTC loss values, one per example in the batch.

See *Connectionist Temporal Classification: Labelling Unsegmented Sequence Data with Recurrent Neural Networks*, A. Graves *et al*. for more information on the definition and the algorithm.

Defined in src/operator/nn/ctc_loss.cc:L100

Value

out The result mx.symbol

Description

.. note:: The existing alias “contrib_CTC Loss” is deprecated.

Usage

mx.symbol.ctc_loss(...)
use.data.lengths
boolean, optional, default=0 Whether the data lengths are decided by 'data_lengths'.
If false, the lengths are equal to the max sequence length.

use.label.lengths
boolean, optional, default=0 Whether the label lengths are decided by 'label_lengths',
or derived from 'padding_mask'. If false, the lengths are derived from the first
occurrence of the value of 'padding_mask'. The value of 'padding_mask' is “0”
when first CTC label is reserved for blank, and “-1” when last label is reserved
for blank. See ‘blank_label’.

blank.label
'first', 'last', optional, default='first' Set the label that is reserved for blank la-
bel. If "first", 0-th label is reserved, and label values for tokens in the vocabulary
are between “1” and “alphabet_size-1”, and the padding mask is “-1”. If "last",
last label value “alphabet_size-1” is reserved for blank label instead, and label
values for tokens in the vocabulary are between “0” and “alphabet_size-2”, and
the padding mask is “0”.

name
string, optional Name of the resulting symbol.

Details
The shapes of the inputs and outputs:
- **data**: '(sequence_length, batch_size, alphabet_size)' - **label**: '(batch_size, label_sequence_length)'
- **out**: '(batch_size)'

The 'data' tensor consists of sequences of activation vectors (without applying softmax), with i-
th channel in the last dimension corresponding to i-th label for i between 0 and alphabet_size-1
(i.e always 0-indexed). Alphabet size should include one additional value reserved for blank label.
When ‘blank_label’ is ‘‘first’’, the “0”-th channel is be reserved for activation of blank label, or
otherwise if it is "last", (alphabet_size-1)-th channel should be reserved for blank label.
“label” is an index matrix of integers. When 'blank_label' is ‘‘first’’, the value 0 is then reserved
for blank label, and should not be passed in this matrix. Otherwise, when 'blank_label' is ‘‘last’’,
the value (alphabet_size-1) is reserved for blank label.

If a sequence of labels is shorter than *label_sequence_length*, use the special padding value at the
end of the sequence to conform it to the correct length. The padding value is ‘0’ when 'blank_label'
is ‘‘first’’, and ‘‘-1’’ otherwise.

For example, suppose the vocabulary is ‘[a, b, c]’, and in one batch we have three sequences 'ba',
'cbb', and 'abac'. When ‘blank_label’ is ‘‘first’’, we can index the labels as ‘‘a’: 1, ‘b’: 2, ‘c’: 3,
and we reserve the 0-th channel for blank label in data tensor. The resulting 'label' tensor should
be padded to be::
[[2, 1, 0, 0], [3, 2, 2, 0], [1, 2, 1, 3]]

When ‘blank_label’ is ‘‘last’’, we can index the labels as ‘‘a’: 0, ‘b’: 1, ‘c’: 2, and we reserve the
channel index 3 for blank label in data tensor. The resulting 'label' tensor should be padded to be::
[[1, 0, -1, -1], [2, 1, 1, -1], [0, 1, 0, 2]]

“out” is a list of CTC loss values, one per example in the batch.
See *Connectionist Temporal Classification: Labelling Unsegmented Sequence Data with Recur-
rent Neural Networks*, A. Graves *et al*. for more information on the definition and the algorithm.
Defined in src/operator/nn/ctc_loss.cc:L100
mx.symbol.Custom

Value

out The result mx.symbol

mx.symbol.cumsum

cumsum: Return the cumulative sum of the elements along a given axis.

Description

Defined in src/operator/numpy/np_cumsum.cc:L70

Usage

mx.symbol.cumsum(...)

Arguments

a NDArray-or-Symbol Input ndarray
axis int or None, optional, default='None' Axis along which the cumulative sum is computed. The default (None) is to compute the cumsum over the flattened array.
dtype None, 'float16', 'float32', 'float64', 'int32', 'int64', 'int8', optional, default='None' Type of the returned array and of the accumulator in which the elements are summed. If dtype is not specified, it defaults to the dtype of a, unless a has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.
name string, optional Name of the resulting symbol.

mx.symbol.Custom

Custom: Apply a custom operator implemented in a frontend language (like Python).

Description

Custom operators should override required methods like ‘forward’ and ‘backward’. The custom operator must be registered before it can be used. Please check the tutorial here: https://mxnet.incubator.apache.org/api/faq/new_op

Usage

mx.symbol.Custom(...)
mx.symbol.Deconvolution

Arguments

- **data**: NDArray-or-Symbol[] Input data for the custom operator.
- **op.type**: string Name of the custom operator. This is the name that is passed to `mx.operator.register` to register the operator.
- **name**: string, optional Name of the resulting symbol.

Details

Defined in src/operator/custom/custom.cc:L547

Value

- **out**: The result mx.symbol

---

**mx.symbol.Deconvolution**

Deconvolution: Computes 1D or 2D transposed convolution (aka fractionally strided convolution) of the input tensor. This operation can be seen as the gradient of Convolution operation with respect to its input. Convolution usually reduces the size of the input. Transposed convolution works the other way, going from a smaller input to a larger output while preserving the connectivity pattern.

Description

Deconvolution: Computes 1D or 2D transposed convolution (aka fractionally strided convolution) of the input tensor. This operation can be seen as the gradient of Convolution operation with respect to its input. Convolution usually reduces the size of the input. Transposed convolution works the other way, going from a smaller input to a larger output while preserving the connectivity pattern.

Usage

mx.symbol.Deconvolution(...)

Arguments

- **data**: NDArray-or-Symbol Input tensor to the deconvolution operation.
- **weight**: NDArray-or-Symbol Weights representing the kernel.
- **bias**: NDArray-or-Symbol Bias added to the result after the deconvolution operation.
- **kernel**: Shape(tuple), required Deconvolution kernel size: (w,), (h, w) or (d, h, w). This is same as the kernel size used for the corresponding convolution
- **stride**: Shape(tuple), optional, default=[] The stride used for the corresponding convolution: (w,), (h, w) or (d, h, w). Defaults to 1 for each dimension.
- **dilate**: Shape(tuple), optional, default=[] Dilation factor for each dimension of the input: (w,), (h, w) or (d, h, w). Defaults to 1 for each dimension.
mx.symbol.degrees

pad: Shape(tuple), optional, default=[] The amount of implicit zero padding added during convolution for each dimension of the input: (w,) or (h, w) or (d, h, w). "(kernel-1)/2" is usually a good choice. If 'target_shape' is set, 'pad' will be ignored and a padding that will generate the target shape will be used. Defaults to no padding.

adj: Shape(tuple), optional, default=[] Adjustment for output shape: (w,) or (d, h, w). If 'target_shape' is set, 'adj' will be ignored and computed accordingly.

target.shape: Shape(tuple), optional, default=[] Shape of the output tensor: (w,) or (d, h, w).

num.filter: int (non-negative), required Number of output filters.

num.group: int (non-negative), optional, default=1 Number of groups partition.

workspace: long (non-negative), optional, default=512 Maximum temporary workspace allowed (MB) in deconvolution. This parameter has two usages. When CUDNN is not used, it determines the effective batch size of the deconvolution kernel. When CUDNN is used, it controls the maximum temporary storage used for tuning the best CUDNN kernel when 'limited_workspace' strategy is used.

no.bias: boolean, optional, default=1 Whether to disable bias parameter.

cudnn.tune: None, 'fastest', 'limited_workspace', 'off', optional, default='None' Whether to pick convolution algorithm by running performance test.

cudnn.off: boolean, optional, default=0 Turn off cudnn for this layer.

layout: None, 'NCDHW', 'NCHW', 'NCW', 'NDHWC', 'NHWC', optional, default='None' Set layout for input, output and weight. Empty for default layout, NCW for 1d, NCHW for 2d and NCDHW for 3d. NHWC and NDHWC are only supported on GPU.

name: string, optional Name of the resulting symbol.

Value

out The result mx.symbol

mx.symbol.degrees

degrees: Converts each element of the input array from radians to degrees.

Description

.. math:: degrees([0, \pi/2, \pi, 3\pi/2, 2\pi]) = [0, 90, 180, 270, 360]

Usage

mx.symbol.degrees(...)
**mx.symbol.depth_to_space**

**Arguments**

- data: NDArray-or-Symbol The input array.
- name: string, optional Name of the resulting symbol.

**Details**

The storage type of "degrees" output depends upon the input storage type:
- degrees(default) = default - degrees(row_sparse) = row_sparse - degrees(csr) = csr

Defined in src/operator/tensor/ElemwiseUnaryOpTrig.cc:L332

**Value**

- out: The result mx.symbol

---

**mx.symbol.depth_to_space**

Rearranges data from depth into blocks of spatial data. Similar to ONNX DepthToSpace operator: https://github.com/onnx/onnx/blob/master/docs/Operators.md#DepthToSpace.

The output is a new tensor where the values from depth dimension are moved in spatial blocks to height and width dimension. The reverse of this operation is "space_to_depth". .. math:: \begin{align*} x' &= reshape(x, [N, \text{block}\_\text{size}, \text{block}\_\text{size}, C / (\text{block}\_\text{size}^2), H \times \text{block}\_\text{size}, W \times \text{block}\_\text{size}]) \\ x' &= transpose(x', [0, 3, 4, 1, 5, 2]) \\ y &= reshape(x', [N, C / (\text{block}\_\text{size}^2), H \times \text{block}\_\text{size}, W \times \text{block}\_\text{size}]) \end{align*}

**Description**

Defined in src/operator/tensor/matrix_op.cc:L972

**Usage**

mx.symbol.depth_to_space(...)

**Arguments**

- data: NDArray-or-Symbol Input ndarray
- block.size: int, required Blocks of [block.size, block.size] are moved
- name: string, optional Name of the resulting symbol.
Value

out The result mx.symbol

mx.symbol.diag

Description

diag"’s behavior depends on the input array dimensions:

Usage

mx.symbol.diag(...) 

Arguments

data NDArray-or-Symbol Input ndarray
k int, optional, default=’0’ Diagonal in question. The default is 0. Use k>0 for diagonals above the main diagonal, and k<0 for diagonals below the main diagonal. If input has shape (S0 S1) k must be between -S0 and S1
axis1 int, optional, default=’0’ The first axis of the sub-arrays of interest. Ignored when the input is a 1-D array.
axis2 int, optional, default=’1’ The second axis of the sub-arrays of interest. Ignored when the input is a 1-D array.
name string, optional Name of the resulting symbol.

Details

- 1-D arrays: constructs a 2-D array with the input as its diagonal, all other elements are zero. - N-D arrays: extracts the diagonals of the sub-arrays with axes specified by “axis1” and “axis2”. The output shape would be decided by removing the axes numbered “axis1” and “axis2” from the input shape and appending to the result a new axis with the size of the diagonals in question.

For example, when the input shape is ’(2, 3, 4, 5)’, “axis1” and “axis2“ are 0 and 2 respectively and “k” is 0, the resulting shape would be ’(3, 5, 2)’.

Examples::
x = [[1, 2, 3], [4, 5, 6]]
diag(x) = [1, 5]
diag(x, k=1) = [2, 6]
diag(x, k=-1) = [4]
x = [1, 2, 3]
diag(x) = [[1, 0, 0], [0, 2, 0], [0, 0, 3]]
diag(x, k=1) = [[0, 1, 0], [0, 0, 2], [0, 0, 0]]
\[
\begin{align*}
\text{diag}(x, k=-1) &= [[0, 0, 0], [1, 0, 0], [0, 2, 0]] \\
x &= [[[1, 2], [3, 4]], [[5, 6], [7, 8]]] \\
\text{diag}(x) &= [[1, 7], [2, 8]] \\
\text{diag}(x, k=1) &= [[3], [4]] \\
\text{diag}(x, \text{axis1}=-2, \text{axis2}=-1) &= [[1, 4], [5, 8]]
\end{align*}
\]

Defined in src/operator/tensor/diag_op.cc:L87

### Value

\[\text{out} \] The result \text{mx.symbol}

---

**mx.symbol.dot**

\textit{dot}: Dot product of two arrays.

---

### Description

“dot”’s behavior depends on the input array dimensions:

### Usage

\[
\text{mx.symbol.dot}(\ldots)
\]

### Arguments

- \textbf{lhs} \text{NDArray-or-Symbol} The first input
- \textbf{rhs} \text{NDArray-or-Symbol} The second input
- \textbf{transpose.a} boolean, optional, default=0 If true then transpose the first input before dot.
- \textbf{transpose.b} boolean, optional, default=0 If true then transpose the second input before dot.
- \textbf{forward.stype} None, ‘csr’, ‘default’, ‘row_sparse’, optional, default=’None’ The desired storage type of the forward output given by user, if the combination of input storage types and this hint does not match any implemented ones, the dot operator will perform fallback operation and still produce an output of the desired storage type.
- \textbf{name} string, optional Name of the resulting symbol.

### Details

- 1-D arrays: inner product of vectors - 2-D arrays: matrix multiplication - N-D arrays: a sum product over the last axis of the first input and the first axis of the second input

For example, given 3-D “x” with shape ‘(n,m,k)’ and “y” with shape ‘(k,r,s)’, the result array will have shape ‘(n,m,r,s)’. It is computed by:

\[
\text{dot}(x, y)[i,j,a,b] = \sum(x[i,j,:]*y[:,a,b])
\]

Example::
x = reshape([0,1,2,3,4,5,6,7], shape=(2,2,2)) y = reshape([7,6,5,4,3,2,1,0], shape=(2,2,2)) dot(x,y)[0,0,1,1] = 0 sum(x[0,0,:]*y[:,1,1]) = 0

The storage type of “dot” output depends on storage types of inputs, transpose option and forward_stype option for output storage type. Implemented sparse operations include:
- dot(default, default, transpose_a=True/False, transpose_b=True/False) = default - dot(csr, default, transpose_a=True) = default - dot(csr, default, transpose_a=True) = row_sparse - dot(csr, default) = default - dot(csr, row_sparse) = default - dot(default, csr) = csr (CPU only) - dot(default, csr, forward_stype='default') = default

If the combination of input storage types and forward_stype does not match any of the above patterns, “dot” will fallback and generate output with default storage.

.. Note::

If the storage type of the lhs is "csr", the storage type of gradient w.r.t rhs will be "row_sparse". Only a subset of optimizers support sparse gradients, including SGD, AdaGrad and Adam. Note that by default lazy updates is turned on, which may perform differently from standard updates. For more details, please check the Optimization API at: https://mxnet.incubator.apache.org/api/python/optimization/optimization.html

Defined in src/operator/tensor/dot.cc:L77

Value

out The result mx.symbol

mx.symbol.Dropout  Dropout:Applies dropout operation to input array.

Description

- During training, each element of the input is set to zero with probability p. The whole array is rescaled by \(1/(1-p)\) to keep the expected sum of the input unchanged.

Usage

mx.symbol.Dropout(...)

Arguments

data  NDArray-or-Symbol Input array to which dropout will be applied.
p  float, optional, default=0.5 Fraction of the input that gets dropped out during training time.
mode  'always', 'training',optional, default='training' Whether to only turn on dropout during training or to also turn on for inference.
axes  Shape(tuple), optional, default=[] Axes for variational dropout kernel.
cudnn_off  boolean or None, optional, default=0 Whether to turn off cudnn in dropout operator. This option is ignored if axes is specified.
name  string, optional Name of the resulting symbol.
**mx.symbol.ElementWiseSum**

**Details**

- During testing, this operator does not change the input if mode is 'training'. If mode is 'always', the same computation as during training will be applied.

Example:

```python
random.seed(998) input_array = array([[3., 0.5, -0.5, 2, 7.], [2., -0.4, 7., 3., 0.2]]) a = symbol.Variable('a') dropout = symbol.Dropout(a, p = 0.2) executor = dropout.simple_bind(a = input_array.shape)
```

## If training executor.forward(is_train = True, a = input_array) executor.outputs [[ 3.75 0.625 -0.25 8.75 ] [ 2.5 -0.5 8.75 3.75 0. ]] 

## If testing executor.forward(is_train = False, a = input_array) executor.outputs [[ 3. 0.5 -0.5 2. 7. ] [ 2. -0.4 7. 3. 0.2 ]]

Defined in src/operator/nn/dropout.cc:L96

**Value**

out The result mx.symbol

---

**mx.symbol.ElementWiseSum**

---

**Description**

.. math:: \text{add}_n(a_1, a_2, ... , a_n) = a_1 + a_2 + ... + a_n

**Usage**

mx.symbol.ElementWiseSum(...)

**Arguments**

- **args**: NDArray-or-Symbol[] Positional input arguments
- **name**: string, optional Name of the resulting symbol.

**Details**

“add_n” is potentially more efficient than calling “add“ by ‘n’ times.

The storage type of “add_n” output depends on storage types of inputs

- `add_n(row_sparse, row_sparse, ..) = row_sparse`
- `add_n(default, csr, default) = default`
- `add_n(any input combinations longer than 4 (>4) with at least one default type) = default`
- `otherwise, “add_n“ falls all inputs back to default storage and generates default storage`

Defined in src/operator/tensor/elementwise_sum.cc:L156

**Value**

out The result mx.symbol
mx.symbol.elemwise_add

elemwise_add: Adds arguments element-wise.

Description
The storage type of "elemwise_add" output depends on storage types of inputs

Usage
mx.symbol.elemwise_add(...)

Arguments
- lhs NDArray-or-Symbol first input
- rhs NDArray-or-Symbol second input
- name string, optional Name of the resulting symbol.

Details
- elemwise_add(row_sparse, row_sparse) = row_sparse
- elemwise_add(csr, csr) = csr
- elemwise_add(default, csr) = default
- elemwise_add(csr, default) = default
- elemwise_add(default, rsp) = default
- elemwise_add(rsp, default) = default
- otherwise, "elemwise_add" generates output with default storage

Value
out The result mx.symbol

mx.symbol.elemwise_div

elemwise_div: Divides arguments element-wise.

Description
The storage type of "elemwise_div" output is always dense

Usage
mx.symbol.elemwise_div(...)

Arguments
- lhs NDArray-or-Symbol first input
- rhs NDArray-or-Symbol second input
- name string, optional Name of the resulting symbol.
mx.symbol.elemwise_mul

**elemwise_mul:** Multiplies arguments element-wise.

---

**Value**

out  The result mx.symbol

---

**Description**

The storage type of “elemwise_mul” output depends on storage types of inputs

**Usage**

mx.symbol.elemwise_mul(...)  

**Arguments**

- **lhs**: NDArray-or-Symbol first input  
- **rhs**: NDArray-or-Symbol second input  
- **name**: string, optional Name of the resulting symbol.

**Details**

- elemwise_mul(default, default) = default - elemwise_mul(row_sparse, row_sparse) = row_sparse - elemwise_mul(default, row_sparse) = row_sparse - elemwise_mul(csr, csr) = csr - otherwise, “elemwise_mul” generates output with default storage

**Value**

out  The result mx.symbol

---

mx.symbol.elemwise_sub

**elemwise_sub:** Subtracts arguments element-wise.

---

**Description**

The storage type of “elemwise_sub” output depends on storage types of inputs

**Usage**

mx.symbol.elemwise_sub(...)
mx.symbol.Embedding

Arguments

- **lhs**: NDArray-or-Symbol first input
- **rhs**: NDArray-or-Symbol second input
- **name**: string, optional Name of the resulting symbol.

Details

- elemwise_sub(row_sparse, row_sparse) = row_sparse - elemwise_sub(csr, csr) = csr - elemwise_sub(default, csr) = default - elemwise_sub(csr, default) = default - elemwise_sub(default, rsp) = default - elemwise_sub(rsp, default) = default - otherwise, "elemwise_sub" generates output with default storage

Value

- out The result mx.symbol

mx.symbol.Embedding

Embedding:Maps integer indices to vector representations (embeddings).

Description

This operator maps words to real-valued vectors in a high-dimensional space, called word embeddings. These embeddings can capture semantic and syntactic properties of the words. For example, it has been noted that in the learned embedding spaces, similar words tend to be close to each other and dissimilar words far apart.

Usage

mx.symbol.Embedding(...)

Arguments

- **data**: NDArray-or-Symbol The input array to the embedding operator.
- **weight**: NDArray-or-Symbol The embedding weight matrix.
- **input.dim**: int, required Vocabulary size of the input indices.
- **output.dim**: int, required Dimension of the embedding vectors.
- **sparse.grad**: boolean, optional, default=0 Compute row sparse gradient in the backward calculation. If set to True, the grad’s storage type is row_sparse.
- **name**: string, optional Name of the resulting symbol.
Details

For an input array of shape (d1, ..., dK), the shape of an output array is (d1, ..., dK, output_dim). All the input values should be integers in the range [0, input_dim).

If the input_dim is ip0 and output_dim is op0, then shape of the embedding weight matrix must be (ip0, op0).

When "sparse_grad" is False, if any index mentioned is too large, it is replaced by the index that addresses the last vector in an embedding matrix. When "sparse_grad" is True, an error will be raised if invalid indices are found.

Examples::

input_dim = 4 output_dim = 5
// Each row in weight matrix y represents a word. So, y = (w0,w1,w2,w3) y = [[ 0., 1., 2., 3., 4.], [ 5., 6., 7., 8., 9.], [ 10., 11., 12., 13., 14.], [ 15., 16., 17., 18., 19.]]
// Input array x represents n-grams(2-gram). So, x = [(w1,w3), (w0,w2)] x = [[ 1., 3.], [ 0., 2.]]
// Mapped input x to its vector representation y. Embedding(x, y, 4, 5) = [[[ 5., 6., 7., 8., 9.], [ 15., 16., 17., 18., 19.]], [[ 0., 1., 2., 3., 4.], [ 10., 11., 12., 13., 14.]]]
The storage type of weight can be either row_sparse or default.

.. Note::

If "sparse_grad" is set to True, the storage type of gradient w.r.t weights will be "row_sparse". Only a subset of optimizers support sparse gradients, including SGD, AdaGrad and Adam. Note that by default lazy updates is turned on, which may perform differently from standard updates. For more details, please check the Optimization API at: https://mxnet.incubator.apache.org/api/python/optimization/optimization.html

Defined in src/operator/tensor/indexing_op.cc:L598

Value

out The result mx.symbol

mx.symbol.erf

erf: Returns element-wise gauss error function of the input.
mx.symbol.erfinv

**Details**

\[
\text{erf}([0, -1., 10.]) = [0., -0.8427, 1.]
\]

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L886

**Value**

out The result mx.symbol

---

mx.symbol.erfinv  

**erfinv:** Returns element-wise inverse gauss error function of the input.

---

**Description**

Example::

**Usage**

mx.symbol.erfinv(...)  

**Arguments**

- **data**  
  NDArray-or-Symbol  
  The input array.

- **name**  
  string, optional  
  Name of the resulting symbol.

**Details**

\[
\text{erfinv}([0, 0.5., -1.]) = [0., 0.4769, -\infty]
\]

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L908

**Value**

out The result mx.symbol
mx.symbol.exp

exp: Returns element-wise exponential value of the input.

Description

.. math:: \exp(x) = e^x \approx 2.718^x

Usage

mx.symbol.exp(...)

Arguments

data NDArray-or-Symbol The input array.
name string, optional Name of the resulting symbol.

Details

Example:

\exp([0, 1, 2]) = [1., 2.71828175, 7.38905621]

The storage type of “exp” output is always dense

Defined in src/operator/tensor/elemwise_unary_op_logexp.cc:L64

Value

out The result mx.symbol

mx.symbol.expand_dims

expand_dims: Inserts a new axis of size 1 into the array shape For example, given “x” with shape “(2,3,4)”, then “expand_dims(x, axis=1)” will return a new array with shape “(2,1,3,4)”.

Description

Defined in src/operator/tensor/matrix_op.cc:L395

Usage

mx.symbol.expand_dims(...)

mx.symbol.expm1

**Arguments**

- **data**
  NDArray-or-Symbol Source input
- **axis**
  int, required Position where new axis is to be inserted. Suppose that the input ‘NDArray’‘s dimension is ‘ndim’, the range of the inserted axis is ‘[-ndim, ndim]’
- **name**
  string, optional Name of the resulting symbol.

**Value**

- **out**
  The result mx.symbol

```
mx.symbol.expm1

expm1:Returns “exp(x) - 1“ computed element-wise on the input.
```

**Description**

This function provides greater precision than “exp(x) - 1“ for small values of “x“.

**Usage**

mx.symbol.expm1(...)

**Arguments**

- **data**
  NDArray-or-Symbol The input array.
- **name**
  string, optional Name of the resulting symbol.

**Details**

The storage type of “expm1“ output depends upon the input storage type:
- expm1(default) = default - expm1(row_sparse) = row_sparse - expm1(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_logexp.cc:L244

**Value**

- **out**
  The result mx.symbol
**mx.symbol.fill_element_0index**

*fill_element_0index*: Fill one element of each line (row for python, column for R/Julia) in lhs according to index indicated by rhs and values indicated by mhs. This function assume rhs uses 0-based index.

**Description**

fill_element_0index: Fill one element of each line (row for python, column for R/Julia) in lhs according to index indicated by rhs and values indicated by mhs. This function assume rhs uses 0-based index.

**Usage**

```python
mx.symbol.fill_element_0index(...)```

**Arguments**

- `lhs` (NDArray): Left operand to the function.
- `mhs` (NDArray): Middle operand to the function.
- `rhs` (NDArray): Right operand to the function.
- `name` (string, optional): Name of the resulting symbol.

**Value**

- `out` (The result): `mx.symbol`

**mx.symbol.fix**

*fix*: Returns element-wise rounded value to the nearest integer towards zero of the input.

**Description**

Example:

**Usage**

```python
mx.symbol.fix(...)```

**Arguments**

- `data` (NDArray-or-Symbol): The input array.
- `name` (string, optional): Name of the resulting symbol.
Details

fix([-2.1, -1.9, 1.9, 2.1]) = [-2., -1., 1., 2.]

The storage type of “fix” output depends upon the input storage type:
- fix(default) = default - fix(row_sparse) = row_sparse - fix(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L874

Value

out The result mx.symbol

mx.symbol.Flatten

Flatten: Flattens the input array into a 2-D array by collapsing the higher dimensions. Note:: ‘Flatten’ is deprecated. Use ‘flatten’ instead. For an input array with shape “(d1, d2, ..., dk)”, ‘flatten’ operation reshapes the input array into an output array of shape “(d1, d2*...*dk)”. Note that the behavior of this function is different from numpy.ndarray.flatten, which behaves similar to mxnet.nd.array.reshape((-1,)). Example:: x = [[1, 2, 3], [4, 5, 6], [7, 8, 9]], [1, 2, 3, 4, 5, 6, 7, 8, 9]], flatten(x) = [[1., 2., 3., 4., 5., 6., 7., 8., 9.], [1., 2., 3., 4., 5., 6., 7., 8., 9.]]

Description

Defined in src/operator/tensor/matrix_op.cc:L250

Usage

mx.symbol.Flatten(...)

Arguments

data NDArray-or-Symbol Input array.

name string, optional Name of the resulting symbol.

Value

out The result mx.symbol
**mx.symbol.flatten**

**flatten:** Flattens the input array into a 2-D array by collapsing the higher dimensions.  
.. note:: ‘Flatten’ is deprecated. Use ‘flatten’ instead. For an input array with shape “(d1, d2, ..., dk)”, ‘flatten’ operation reshapes the input array into an output array of shape “(d1, d2*...*dk)”. Note that the behavior of this function is different from numpy.ndarray.flatten, which behaves similar to mxnet.nd.array.reshape((-1,)). Example:: 

```python
x = [[[1,2,3], [4,5,6], [7,8,9]], [[1,2,3], [4,5,6], [7,8,9]]] 
flatten(x) = [[[1., 2., 3., 4., 5., 6., 7., 8., 9.], [1., 2., 3., 4., 5., 6., 7., 8., 9.]]
```

**Description**

Defined in src/operator/tensor/matrix_op.cc:L250

**Usage**

```
mx.symbol.flatten(...) 
```

**Arguments**

- **data**: NDArray-or-Symbol Input array.
- **name**: string, optional Name of the resulting symbol.

**Value**

```
out The result mx.symbol
```

**mx.symbol.flip**

**flip:** Reverses the order of elements along given axis while preserving array shape. Note: reverse and flip are equivalent. We use reverse in the following examples. Examples::

```python
x = [[0., 1., 2., 3.], [5., 6., 7., 8., 9.]] 
reverse(x, axis=0) = [[5., 6., 7., 8., 9.], [0., 1., 2., 3.]] 
reverse(x, axis=1) = [[4., 3., 2., 1.], [9., 8., 7., 6.]]
```

**Description**

Defined in src/operator/tensor/matrix_op.cc:L832

**Usage**

```
mx.symbol.flip(...) 
```
mx.symbol.floor

**Arguments**

- **data**: NDArray-or-Symbol Input data array
- **axis**: Shape(tuple), required The axis which to reverse elements.
- **name**: string, optional Name of the resulting symbol.

**Value**

- **out**: The result mx.symbol

---

**mx.symbol.floor**

```
floor:Returns element-wise floor of the input.
```

**Description**

The floor of the scalar x is the largest integer i, such that i <= x.

**Usage**

```
mx.symbol.floor(...)
```

**Arguments**

- **data**: NDArray-or-Symbol The input array.
- **name**: string, optional Name of the resulting symbol.

**Details**

Example::

```
floor([-2.1, -1.9, 1.5, 1.9, 2.1]) = [-3., -2., 1., 1., 2.]
```

The storage type of “floor“ output depends upon the input storage type:

- floor(default) = default - floor(row_sparse) = row_sparse - floor(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L836

**Value**

- **out**: The result mx.symbol

Description

.. math::

Usage

mx.symbol.ftml_update(...)

Arguments

weight NDArray-or-Symbol Weight
grad NDArray-or-Symbol Gradient
d NDArray-or-Symbol Internal state “d_t”
v NDArray-or-Symbol Internal state “v_t”
z NDArray-or-Symbol Internal state “z_t”
lr float, required Learning rate.
beta1 float, optional, default=0.600000024 Generally close to 0.5.
beta2 float, optional, default=0.999000013 Generally close to 1.
epsilon double, optional, default=9.999999392252903e-09 Epsilon to prevent div 0.
t int, required Number of update.
wd float, optional, default=0 Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
rescale_grad float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
clip_grad float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient] If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).
name string, optional Name of the resulting symbol.

Details

\[ g_t = \nabla J(W_{t-1}) \] \[ v_{t} = \beta_2 v_{t-1} + (1 - \beta_2) g_t^2 \] \[ d_{t} = \frac{1 - \beta_1^t}{\sqrt{v_{t} - \beta_2^t + \epsilon}} \sigma_{t} \] \[ \sigma_t = d_{t} - \beta_1 d_{t-1} \] \[ z_{t} = \beta_1 z_{t-1} + (1 - \beta_1^t) g_t - \sigma_t \] \[ W_t = - \frac{z_t}{d_t} \]

Defined in src/operator/optimizer_op.cc:L640

<td>float, optional, default=1 Clip gradient to the range of [-clip.gradient, clip.gradient]</td>
</tr>
<tr>
<td>name</td>
<td>string, optional Name of the resulting symbol.</td>
</tr>
</tbody>
</table>

Details

rescaled_grad = clip(grad * rescale_grad, clip_gradient) 
z += rescaled_grad - (sqrt(n + rescaled_grad**2) - sqrt(n)) * weight / learning_rate 
n += rescaled_grad**2 
w = (sign(z) * lamda1 - z) / ((beta + sqrt(n)) / learning_rate + wd) * (abs(z) > lamda1)

If w, z and n are all of “row_sparse” storage type, only the row slices whose indices appear in grad.indices are updated (for w, z and n):

n[row] += rescaled_grad[row]**2 
w[row] = (sign(z[row]) * lamda1 - z[row]) / ((beta + sqrt(n[row])) / learning_rate + wd) * (abs(z[row]) > lamda1)

Defined in src/operator/optimizer_op.cc:L876
FullyConnected: Applies a linear transformation: \( Y = XW^T + b \).

### Description

If "flatten" is set to be true, then the shapes are:

### Usage

```python
mx.symbol.FullyConnected(...)
```

### Arguments

- **data**: NDArray-or-Symbol Input data.
- **weight**: NDArray-or-Symbol Weight matrix.
- **bias**: NDArray-or-Symbol Bias parameter.
- **num.hidden**: int, required Number of hidden nodes of the output.
- **no.bias**: boolean, optional, default=0 Whether to disable bias parameter.
- **flatten**: boolean, optional, default=1 Whether to collapse all but the first axis of the input data tensor.
- **name**: string, optional Name of the resulting symbol.

### Details

- **data**: '(batch_size, x1, x2, ..., xn)' - **weight**: '(num_hidden, x1 * x2 * ... * xn)' - **bias**: '(num_hidden,)' - **out**: '(batch_size, num_hidden)'

If "flatten" is set to be false, then the shapes are:

- **data**: '(x1, x2, ..., xn, input_dim)' - **weight**: '(num_hidden, input_dim)' - **bias**: '(num_hidden,)' - **out**: '(x1, x2, ..., xn, num_hidden)'

The learnable parameters include both "weight" and "bias".

If "no.bias" is set to be true, then the "bias" term is ignored.

.. Note::

The sparse support for FullyConnected is limited to forward evaluation with 'row_sparse' weight and bias, where the length of 'weight.indices' and 'bias.indices' must be equal to 'num_hidden'. This could be useful for model inference with 'row_sparse' weights trained with importance sampling or noise contrastive estimation.

To compute linear transformation with 'csr' sparse data, sparse.dot is recommended instead of sparse.FullyConnected.

Defined in src/operator/nn/fully_connected.cc:L287
**mx.symbol.gamma**

.gamma: Returns the gamma function (extension of the factorial function to the reals), computed element-wise on the input array.

**Description**

The storage type of “gamma“ output is always dense.

**Usage**

`mx.symbol.gamma(...)`

**Arguments**

- **data**: NDArray-or-Symbol The input array.
- **name**: string, optional Name of the resulting symbol.

**Value**

out The result mx.symbol

---

**mx.symbol.gammaln**

**gammaln: Returns element-wise log of the absolute value of the gamma function of the input.**

**Description**

The storage type of “gammaln“ output is always dense.

**Usage**

`mx.symbol.gammaln(...)`

**Arguments**

- **data**: NDArray-or-Symbol The input array.
- **name**: string, optional Name of the resulting symbol.

**Value**

out The result mx.symbol
mx.symbol.gather_nd

**Description**

Given ‘data’ with shape ‘(X_0, X_1, ..., X_N-1)’ and indices with shape ‘(M, Y_0, ..., Y_K-1)’, the output will have shape ‘(Y_0, ..., Y_K-1, X_M, ..., X_N-1)’, where ‘M <= N’. If ‘M == N’, output shape will simply be ‘(Y_0, ..., Y_K-1)’.

**Usage**

`mx.symbol.gather_nd(...)`

**Arguments**

- `data` NDArray-or-Symbol data
- `indices` NDArray-or-Symbol indices
- `name` string, optional Name of the resulting symbol.

**Details**

The elements in output is defined as follows:

\[ \text{output}[y_0, ..., y_{K-1}, x_M, ..., x_{N-1}] = \text{data}[\text{indices}[0, y_0, ..., y_{K-1}], ..., \text{indices}[M-1, y_0, ..., y_{K-1}], x_M, ..., x_{N-1}] \]

**Examples**:

- `data = [[0, 1], [2, 3]]` `indices = [[1, 0], [0, 1]]` `gather_nd(data, indices) = [2, 3, 0]`
- `data = [[[1, 2], [3, 4]], [[5, 6], [7, 8]]]` `indices = [[0, 1], [1, 0]]` `gather_nd(data, indices) = [[3, 4], [5, 6]]`

**Value**

- `out` The result mx.symbol

mx.symbol.GridGenerator

**Description**

GridGenerator: Generates 2D sampling grid for bilinear sampling.

**Usage**

`mx.symbol.GridGenerator`
**mx.symbol.Group**

Create a symbol that groups symbols together.

**Usage**

```python
mx.symbol.GridGenerator(...)```

**Arguments**

- `data` (NDArray-or-Symbol): Input data to the function.
- `transform.type` ('affine', 'warp', required): The type of transformation. For 'affine', input data should be an affine matrix of size (batch, 6). For 'warp', input data should be an optical flow of size (batch, 2, h, w).
- `target.shape` (Shape(tuple), optional, default=[0,0]): Specifies the output shape (H, W). This is required if transformation type is 'affine'. If transformation type is 'warp', this parameter is ignored.
- `name` (string, optional): Name of the resulting symbol.

**Value**

```python
out The result mx.symbol```

---

**mx.symbol.Group**

Create a symbol that groups symbols together.

**Description**

Create a symbol that groups symbols together.

**Usage**

```python
mx.symbol.Group(...)```

**Arguments**

- `kwarg` (Variable length of symbols or list of symbol): Variable length of symbols or list of symbol.

**Value**

The result symbol
mx.symbol.GroupNorm  

*GroupNorm*: Group normalization.

**Description**

The input channels are separated into “num_groups” groups, each containing “num_channels / num_groups” channels. The mean and standard-deviation are calculated separately over the each group.

**Usage**

```python
mx.symbol.GroupNorm(...)
```

**Arguments**

- **data**: NDArray-or-Symbol Input data
- **gamma**: NDArray-or-Symbol gamma array
- **beta**: NDArray-or-Symbol beta array
- **num.groups**: int, optional, default='1' Total number of groups.
- **eps**: float, optional, default=9.99999975e-06 An ‘epsilon’ parameter to prevent division by 0.
- **output.mean.var**: boolean, optional, default=0 Output the mean and std calculated along the given axis.
- **name**: string, optional Name of the resulting symbol.

**Details**

.. math::

   data = data.reshape((N, num_groups, C // num_groups, ...))
   out = \frac{data - mean(data, axis)\sqrt{var(data, axis)}}{\epsilon} + \gamma + \beta

Both “gamma” and “beta” are learnable parameters.

Defined in src/operator/nn/group_norm.cc:L77

**Value**

out The result mx.symbol
**mx.symbol.hard_sigmoid**

`hard_sigmoid`: Computes hard sigmoid of `x` element-wise.

**Description**

.. math:: y = \max(0, \min(1, \alpha \times x + \beta))

**Usage**

mx.symbol.hard_sigmoid(...)

**Arguments**

- `data` : NDArray-or-Symbol The input array.
- `alpha` : float, optional, default=0.200000003 Slope of hard sigmoid
- `beta` : float, optional, default=0.5 Bias of hard sigmoid.
- `name` : string, optional Name of the resulting symbol.

**Details**

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L161

**Value**

out The result mx.symbol

---

**mx.symbol.identity**

`identity`: Returns a copy of the input.

**Description**

From:src/operator/tensor/elemwise_unary_op_basic.cc:244

**Usage**

mx.symbol.identity(...)

**Arguments**

- `data` : NDArray-or-Symbol The input array.
- `name` : string, optional Name of the resulting symbol.

**Value**

out The result mx.symbol
**mx.symbol.IdentityAttachKLSparseReg**

IdentityAttachKLSparseReg: Apply a sparse regularization to the output a sigmoid activation function.

**Description**

IdentityAttachKLSparseReg: Apply a sparse regularization to the output a sigmoid activation function.

**Usage**

mx.symbol.IdentityAttachKLSparseReg(...)

**Arguments**

- **data**: NDArray-or-Symbol Input data.
- **sparseness.target**: float, optional, default=0.100000001 The sparseness target
- **penalty**: float, optional, default=0.00100000005 The tradeoff parameter for the sparseness penalty
- **momentum**: float, optional, default=0.899999976 The momentum for running average
- **name**: string, optional Name of the resulting symbol.

**Value**

out The result mx.symbol

**mx.symbol.im2col**

im2col: Extract sliding blocks from input array.

**Description**

This operator is used in vanilla convolution implementation to transform the sliding blocks on image to column matrix, then the convolution operation can be computed by matrix multiplication between column and convolution weight. Due to the close relation between im2col and convolution, the concept of **kernel**, **stride**, **dilate** and **pad** in this operator are inherited from convolution operation.

**Usage**

mx.symbol.im2col(...)

Arguments

data    NDArray-or-Symbol Input array to extract sliding blocks.
kernel  Shape(tuple), required Sliding kernel size: (w,), (h, w) or (d, h, w).
stride  Shape(tuple), optional, default=[] The stride between adjacent sliding blocks in
        spatial dimension: (w,), (h, w) or (d, h, w). Defaults to 1 for each dimension.
dilate  Shape(tuple), optional, default=[] The spacing between adjacent kernel points:
        (w,), (h, w) or (d, h, w). Defaults to 1 for each dimension.
pad     Shape(tuple), optional, default=[] The zero-value padding size on both sides of
        spatial dimension: (w,), (h, w) or (d, h, w). Defaults to no padding.
name    string, optional Name of the resulting symbol.

Details

Given the input data of shape :math:`(N, C, *)`, where :math:`N` is the batch size, :math:`C` is the
channel size, and :math:`*` is the arbitrary spatial dimension, the output column array is always
with shape :math:`(N, C \times \prod(\text{kernel}), W)`, where :math:`C \times \prod(\text{kernel})`
is the block size, and :math:`W` is the block number which is the spatial size of the convolution
output with same input parameters. Only 1-D, 2-D and 3-D of spatial dimension is supported in this
operator.

Defined in src/operator/nn/im2col.cc:L100

Value

out The result mx.symbol

Inference the shape of arguments, outputs, and auxiliary states.

Description

Inference the shape of arguments, outputs, and auxiliary states.

Usage

mx.symbol.infer.shape(symbol, ...)

Arguments

symbol The mx.symbol object
**mx.symbol.InstanceNorm**

*InstanceNorm:* Applies instance normalization to the n-dimensional input array.

---

**Description**

This operator takes an n-dimensional input array where (n>2) and normalizes the input using the following formula:

**Usage**

mx.symbol.InstanceNorm(...)

**Arguments**

- **data**
  - NDArray-or-Symbol An n-dimensional input array (n > 2) of the form [batch, channel, spatial_dim1, spatial_dim2, ...].

- **gamma**
  - NDArray-or-Symbol A vector of length 'channel', which multiplies the normalized input.

- **beta**
  - NDArray-or-Symbol A vector of length 'channel', which is added to the product of the normalized input and the weight.

- **eps**
  - float, optional, default=0.00100000005 An 'epsilon' parameter to prevent division by 0.

- **name**
  - string, optional Name of the resulting symbol.

**Details**

.. math::
   \text{out} = \frac{x - \text{mean}[\text{data}]}{\sqrt{\text{Var}[\text{data}]} + \epsilon} \cdot \gamma + \beta

This layer is similar to batch normalization layer (‘BatchNorm’) with two differences: first, the normalization is carried out per example (instance), not over a batch. Second, the same normalization is applied both at test and train time. This operation is also known as ‘contrast normalization’.

If the input data is of shape [batch, channel, spatial_dim1, spacial_dim2, ...], ‘gamma’ and ‘beta’ parameters must be vectors of shape [channel].

This implementation is based on this paper [1].

**Examples::**

// Input of shape (2,1,2) x = [[[ 1.1, 2.2]], [[ 3.3, 4.4]]]
// gamma parameter of length 1 gamma = [1.5]
// beta parameter of length 1 beta = [0.5]
// Instance normalization is calculated with the above formula
InstanceNorm(x, gamma, beta) = [[[-0.997527 , 1.99752665]], [[-0.99752653, 1.99752724]]]
Defined in src/operator/instance_norm.cc:L95

Value

out The result mx.symbol

mx.symbol.khatri_rao

khatri_rao:Computes the Khatri-Rao product of the input matrices.

Description

Given a collection of \( n \) input matrices,

Usage

mx.symbol.khatri_rao(...)

Arguments

args NDArray-or-Symbol[] Positional input matrices
name string, optional Name of the resulting symbol.

Details

.. math:: \ A_1 \in \mathbb{R}^{M_1 \times N}, \ldots, \ A_n \in \mathbb{R}^{M_n \times N},
the (column-wise) Khatri-Rao product is defined as the matrix,

.. math:: X = A_1 \otimes \cdots \otimes A_n \in \mathbb{R}^{(M_1 \cdot \cdots \cdot M_n) \times N},
where the :math:`k` th column is equal to the column-wise outer product :math:`A_1_k \otimes \cdots \otimes A_n_k` where :math:`A_i_k` is the kth column of the ith matrix.

Example::

>>> A = mx.nd.array([[1, -1], [2, -3]])
>>> B = mx.nd.array([[1, 4], [2, 5], [3, 6]])
>>> C = mx.nd.khatri_rao(A, B)
>>> print(C.asnumpy())
[[ 1. -4.]
 [ 2. -12.]
 [ 4. -20.]
 [ 6. -28.]]

Defined in src/operator/contrib/krprod.cc:L108

Value

out The result mx.symbol
mx.symbol.L2Normalization

L2Normalization: Normalize the input array using the L2 norm.

Description

For 1-D NDArray, it computes:

Usage

mx.symbol.L2Normalization(...)

Arguments

data: NDArray-or-Symbol Input array to normalize.
eps: float, optional, default=1.00000001e-10 A small constant for numerical stability.
mode: 'channel', 'instance', 'spatial', optional, default='instance' Specify the dimension along which to compute L2 norm.
name: string, optional Name of the resulting symbol.

Details

out = data / sqrt(sum(data ** 2) + eps)

For N-D NDArray, if the input array has shape (N, N, ..., N), with "mode" = "instance", it normalizes each instance in the multidimensional array by its L2 norm.:

for i in 0...N out[i,:,:,:,:,...] = data[i,:,:,:,:,...] / sqrt(sum(data[i,:,:,:,:,...] ** 2) + eps)

with "mode" = "channel", it normalizes each channel in the array by its L2 norm.:

for i in 0...N out[:,:,i,:,:,:,:,...] = data[:,:,i,:,:,:,:,...] / sqrt(sum(data[:,:,i,:,:,:,:,...] ** 2) + eps)

with "mode" = "spatial", it normalizes the cross channel norm for each position in the array by its L2 norm.:

for dim in 2...N for i in 0...N out[....,i,...,...] = take(out, indices=i, axis=dim) / sqrt(sum(take(out, indices=i, axis=dim) ** 2) + eps) -dim-

Example:

```python
x = [[[1.2], [3.4]], [[2.2], [5.6]]]
L2Normalization(x, mode='instance')=[[[[0.31622776 0.44721359] [0.60000002 0.80000001]]
[0.6401844 0.76822126]]
L2Normalization(x, mode='channel')=[[[[0.31622776 0.44721359] [0.94868326 0.94868326]]
[0.70710677 0.70710677]]
L2Normalization(x, mode='spatial')=[[[[0.31622776 0.44721359] [0.60000002 0.80000001]]
[0.6401844 0.76822126]]
```

mx.symbol.lamb_update_phase1

**lamb_update_phase1**: Phase I of lamb update it performs the following operations and returns g:

Description

Usage

mx.symbol.lamb_update_phase1(...)

Arguments

- **weight**: NDArray-or-Symbol Weight
- **grad**: NDArray-or-Symbol Gradient
- **mean**: NDArray-or-Symbol Moving mean
- **var**: NDArray-or-Symbol Moving variance
- **beta1**: float, optional, default=0.899999976 The decay rate for the 1st moment estimates.
- **beta2**: float, optional, default=0.999000013 The decay rate for the 2nd moment estimates.
- **epsilon**: float, optional, default=9.99999997e-07 A small constant for numerical stability.
- **t**: int, required Index update count.
- **bias.correction**: boolean, optional, default=1 Whether to use bias correction.
- **wd**: float, required Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
- **rescale.grad**: float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
- **clip.gradient**: float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient] If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).
- **name**: string, optional Name of the resulting symbol.
mx.symbol.lamb_update_phase2

Details

.. math:: \begin{align*}
    \text{grad} &= \text{grad} \times \text{rescale\_grad} \\
    \text{mean} &= \beta_1 \times \text{mean} + (1 - \beta_1) \times \text{grad} \\
    \text{variance} &= \beta_2 \times \text{variance} + (1 - \beta_2) \times \text{grad}^2 \\
    \text{if (bias\_correction)} \text{then} \text{mean\_hat} &= \frac{\text{mean}}{1 - \beta_1^t} \\
    \text{var\_hat} &= \frac{\text{variance}}{1 - \beta_2^t} \\
    \text{if (bias\_correction)} \text{then} \text{g} &= \frac{\text{mean\_hat}}{\sqrt{\text{var\_hat} + \text{epsilon}}} + \text{wd} \times \text{weight} \\
    \text{else} \text{g} &= \frac{\text{mean}}{\sqrt{\text{var\_data} + \text{epsilon}}} + \text{wd} \times \text{weight} \\
\end{align*}

Defined in src/operator/optimizer_op.cc:L953

Value

out The result mx.symbol

mx.symbol.lamb_update_phase2: Phase II of lamb update it performs the following operations and updates grad.

Description

Usage

mx.symbol.lamb_update_phase2(...)

Arguments

weight: NDArray-or-Symbol Weight

g: NDArray-or-Symbol Output of lamb_update_phase 1

r1: NDArray-or-Symbol r1

r2: NDArray-or-Symbol r2

lr: float, required Learning rate

lower\_bound: float, optional, default=-1 Lower limit of norm of weight. If lower_bound <= 0,

Upper limit is not set

upper\_bound: float, optional, default=-1 Upper limit of norm of weight. If upper_bound <= 0,

Upper limit is not set

name: string, optional Name of the resulting symbol.

Details

.. math:: \begin{align*}
    \text{if (lower\_bound >= 0)} \text{then} r1 &= \max(r1, \text{lower\_bound}) \\
    \text{if (upper\_bound >= 0)} \text{then} r1 &= \max(r1, \text{upper\_bound}) \\
    \text{if (r1 == 0 or r2 == 0)} \text{then} lr &= lr \text{ else} lr &= lr \times \frac{r1}{r2} \text{ weight} = \text{weight} - lr \times g \\
\end{align*}

Defined in src/operator/optimizer_op.cc:L992
mx.symbol.LayerNorm

**Value**

out The result mx.symbol

**mx.symbol.LayerNorm** *LayerNorm: Layer normalization.*

**Description**

Normalizes the channels of the input tensor by mean and variance, and applies a scale “gamma” as well as offset “beta”.

**Usage**

mx.symbol.LayerNorm(...)

**Arguments**

- **data**: NDArray-or-Symbol Input data to layer normalization
- **gamma**: NDArray-or-Symbol gamma array
- **beta**: NDArray-or-Symbol beta array
- **axis**: int, optional, default='\-1' The axis to perform layer normalization. Usually, this should be be axis of the channel dimension. Negative values means indexing from right to left.
- **eps**: float, optional, default=9.99999975e-06 An ‘epsilon’ parameter to prevent division by 0.
- **output.mean.var**: boolean, optional, default=0 Output the mean and std calculated along the given axis.
- **name**: string, optional Name of the resulting symbol.

**Details**

Assume the input has more than one dimension and we normalize along axis 1. We first compute the mean and variance along this axis and then compute the normalized output, which has the same shape as input, as following:

\[
\text{out} = \frac{\text{data} - \text{mean(data, axis)}}{\sqrt{\text{var(data, axis)}}} + \epsilon \cdot \text{gamma} + \text{beta}
\]

Both “gamma” and “beta” are learnable parameters.

Unlike BatchNorm and InstanceNorm, the *mean* and *var* are computed along the channel dimension.

Assume the input has size *k* on axis 1, then both “gamma” and “beta” have shape *(k,)*. If “output_mean_var” is set to be true, then outputs both “data_mean” and “data_std”. Note that no gradient will be passed through these two outputs.
The parameter "axis" specifies which axis of the input shape denotes the 'channel' (separately normalized groups). The default is -1, which sets the channel axis to be the last item in the input shape.

Defined in src/operator/nn/layer_norm.cc:L159

Value

out The result mx.symbol

mx.symbol.LeakyReLU

Description

Leaky ReLUs attempt to fix the "dying ReLU" problem by allowing a small 'slope' when the input is negative and has a slope of one when input is positive.

Usage

mx.symbol.LeakyReLU(...)

Arguments

data NDArray-or-Symbol Input data to activation function.
gamma NDArray-or-Symbol Input data to activation function.
act.type 'elu', 'gelu', 'leaky', 'prelu', 'rrelu', 'selu'.optional, default='leaky' Activation function to be applied.
slope float, optional, default=0.25 Init slope for the activation. (For leaky and elu only)
lower.bound float, optional, default=0.125 Lower bound of random slope. (For rrelu only)
upper.bound float, optional, default=0.333999991 Upper bound of random slope. (For rrelu only)
name string, optional Name of the resulting symbol.

Details

The following modified ReLU Activation functions are supported:
- *elu*: Exponential Linear Unit. \( y = x > 0 \ ? \ x : \ \text{slope} \times (\exp(x)-1) \). *elu*: Scaled Exponential Linear Unit. \( y = \text{lambda} \times (x > 0 \ ? \ x : \ \alpha \times (\exp(x)-1)) \) where \( \text{lambda} = 1.0507009873554804934193349852946\) and \( \alpha = 1.6732632423543772848170429916717\).
- *leaky*: Leaky ReLU. \( y = x > 0 \ ? \ x : \ \text{slope} \times x \). *prelu*: Parametric ReLU. This is same as *leaky* except that 'slope' is learnt during training. *rrelu*: Randomized ReLU. same as *leaky* but the 'slope' is uniformly and randomly chosen from \( [\text{lower bound}, \text{upper bound}] \) for training, while fixed to be \( ((\text{lower bound}+\text{upper bound})/2) \) for inference.

Defined in src/operator/leaky_relu.cc:L163
mx.symbol.linalg_det

Value

out The result mx.symbol

mx.symbol.linalg_det linalg_det: Compute the determinant of a matrix. Input is a tensor *A* of dimension *n >= 2*.

Description

If *n=2*, *A* is a square matrix. We compute:

Usage

mx.symbol.linalg_det(...)  

Arguments

A NDArray-or-Symbol Tensor of square matrix  
name string, optional Name of the resulting symbol.

Details

*out* = *det(A)*  
If *n>2*, *det* is performed separately on the trailing two dimensions for all inputs (batch mode).  
.. note:: The operator supports float32 and float64 data types only.  
.. note:: There is no gradient backwared when A is non-invertible (which is equivalent to det(A) = 0) because zero is rarely hit upon in float point computation and the Jacobi’s formula on determinant gradient is not computa- 
tionally efficient when A is non-invertible.

Examples:: 
Single matrix determinant A = [[1., 4.], [2., 3.]] det(A) = [-5.]
Batch matrix determinant A = [[[1., 4.], [2., 3.]], [[2., 3.], [1., 4.]]] det(A) = [-5., 5.]

Defined in src/operator/tensor/la_op.cc:L975

Value

out The result mx.symbol
mx.symbol.linalg_extractdiag

.linalg_extractdiag: Extracts the diagonal entries of a square matrix.
Input is a tensor *A* of dimension *n >= 2*.

Description

If *n=2*, then *A* represents a single square matrix which diagonal elements get extracted as a 1-dimensional tensor.

Usage

mx.symbol.linalg_extractdiag(...)

Arguments

A
NDArray-or-Symbol Tensor of square matrices

offset
int, optional, default='0' Offset of the diagonal versus the main diagonal. 0 corresponds to the main diagonal, a negative/positive value to diagonals below/above the main diagonal.

name
string, optional Name of the resulting symbol.

Details

If *n>2*, then *A* represents a batch of square matrices on the trailing two dimensions. The extracted diagonals are returned as an *n-1*-dimensional tensor.

.. note:: The operator supports float32 and float64 data types only.

Examples::

Single matrix diagonal extraction A = [[1.0, 2.0], [3.0, 4.0]]
extractdiag(A) = [1.0, 4.0]
extractdiag(A, 1) = [2.0]

Batch matrix diagonal extraction A = [[[1.0, 2.0], [3.0, 4.0]], [[5.0, 6.0], [7.0, 8.0]]]
extractdiag(A) = [[1.0, 4.0], [5.0, 8.0]]

Defined in src/operator/tensor/la_op.cc:L495

Value

out The result mx.symbol
mx.symbol.linalg_extracttrian

**Description**

If $n=2$, then $A$ represents a single square matrix from which a triangular sub-matrix is extracted as a 1-dimensional tensor.

**Usage**

```
mx.symbol.linalg_extracttrian(...)  
```

**Arguments**

- **A**: NDArray-or-Symbol Tensor of square matrices
- **offset**: int, optional, default='0' Offset of the diagonal versus the main diagonal. 0 corresponds to the main diagonal, a negative/positive value to diagonals below/above the main diagonal.
- **lower**: boolean, optional, default=1 Refer to the lower triangular matrix if lower=true, refer to the upper otherwise. Only relevant when offset=0
- **name**: string, optional Name of the resulting symbol.

**Details**

If $n>2$, then $A$ represents a batch of square matrices on the trailing two dimensions. The extracted triangular sub-matrices are returned as an $n-1$-dimensional tensor.

The *offset* and *lower* parameters determine the triangle to be extracted:

- When *offset = 0* either the lower or upper triangle with respect to the main diagonal is extracted depending on the value of parameter *lower*.  
- When *offset = k > 0* the upper triangle with respect to the k-th diagonal above the main diagonal is extracted.  
- When *offset = k < 0* the lower triangle with respect to the k-th diagonal below the main diagonal is extracted.

.. note:: The operator supports float32 and float64 data types only.

**Examples:**

Single triagonal extraction $A = \begin{bmatrix} 1.0 & 2.0 \\ 3.0 & 4.0 \end{bmatrix}$

```
extracttrian(A) = [1.0, 3.0, 4.0] extracttrian(A, lower=False) = [1.0, 2.0, 4.0] extracttrian(A, 1) = [2.0] extracttrian(A, -1) = [3.0]
```

Batch triagonal extraction $A = \begin{bmatrix} 1.0 & 2.0 \\ 3.0 & 4.0 \end{bmatrix}, \begin{bmatrix} 5.0 & 6.0 \\ 7.0 & 8.0 \end{bmatrix}$

```
extracttrian(A) = \begin{bmatrix} 1.0, 3.0, 4.0 \\ 5.0, 7.0, 8.0 \end{bmatrix}
```

Defined in src/operator/tensor/la_op.cc:L605

**Value**

```
out The result mx.symbol
```
**mx.symbol.linalg_gelqf**

linalg_gelqf: LQ factorization for general matrix. Input is a tensor *A* of dimension *n >= 2*.

### Description

If *n=2*, we compute the LQ factorization (LAPACK *gelqf*, followed by *orglq*). *A* must have shape *(x, y)* with *x <= y*, and must have full rank *=x*. The LQ factorization consists of *L* with shape *(x, x)* and *Q* with shape *(x, y)*, so that:

### Usage

mx.symbol.linalg_gelqf(...)

### Arguments

- **A**: NDArray-or-Symbol Tensor of input matrices to be factorized
- **name**: string, optional Name of the resulting symbol.

### Details

* A* = *L* \* *Q*

Here, *L* is lower triangular (upper triangle equal to zero) with nonzero diagonal, and *Q* is row-orthonormal, meaning that:

* Q* \* *Q*

is equal to the identity matrix of shape *(x, x)*.

If *n>2*, *gelqf* is performed separately on the trailing two dimensions for all inputs (batch mode).

.. note:: The operator supports float32 and float64 data types only.

### Examples:

**Single LQ factorization**

A = [[1., 2., 3.], [4., 5., 6.]]

Q, L = gelqf(A)

Q = [[-0.26726124, -0.53452248, -0.80178373],
     [0.87287156, 0.21821789, -0.43643578]]

L = [[-3.74165739, 0.],
     [-8.55235974, 1.96396101]]

**Batch LQ factorization**

Q, L = gelqf(A)

Q = [[[-0.26726124, -0.53452248, -0.80178373],
      [0.87287156, 0.21821789, -0.43643578]],
     [[-0.50257071, -0.57436653, -0.64616234],
      [0.7620735, 0.05862104, -0.64483142]],
     [[-13.92838828, 0.],
      [-19.09768702, 0.52758934]]]

### Defined in

Defined in src/operator/tensor/la_op.cc:L798

### Value

out The result mx.symbol
mx.symbol.linalg_gemm  

**Description**

If \( n=2 \), the BLAS3 function \( \text{gemm} \) is performed:

**Usage**

```python
mx.symbol.linalg_gemm(...)
```

**Arguments**

- **A**: NDArray-or-Symbol Tensor of input matrices
- **B**: NDArray-or-Symbol Tensor of input matrices
- **C**: NDArray-or-Symbol Tensor of input matrices
- **transpose.a**: boolean, optional, default=0 Multiply with transposed of first input (A).
- **transpose.b**: boolean, optional, default=0 Multiply with transposed of second input (B).
- **alpha**: double, optional, default=1 Scalar factor multiplied with A*B.
- **beta**: double, optional, default=1 Scalar factor multiplied with C.
- **axis**: int, optional, default='-2' Axis corresponding to the matrix rows.
- **name**: string, optional Name of the resulting symbol.

**Details**

\[ \text{out} = \alpha \times \text{op}(A) \times \text{op}(B) + \beta \times C \]

Here, \( \alpha \) and \( \beta \) are scalar parameters, and \( \text{op}() \) is either the identity or matrix transposition (depending on \( \text{transpose.a} \), \( \text{transpose.b} \)).

If \( n>2 \), \( \text{gemm} \) is performed separately for a batch of matrices. The column indices of the matrices are given by the last dimensions of the tensors, the row indices by the axis specified with the \( \text{axis} \) parameter.

For a non-default axis parameter, the operation performed is equivalent to a series of swapaxes/gemm/swapaxes calls. For example let \( *A*, *B*, *C* be 5 dimensional tensors. Then \( \text{gemm}(A, B, C, \text{axis}=1) \) is equivalent to the following without the overhead of the additional swapaxis operations:

\[
\begin{align*}
A1 &= \text{swapaxes}(A, \text{dim1}=1, \text{dim2}=3) \\
B1 &= \text{swapaxes}(B, \text{dim1}=1, \text{dim2}=3) \\
C &= \text{gemm}(A1, B1, C) \\
C &= \text{swapaxis}(C, \text{dim1}=1, \text{dim2}=3)
\end{align*}
\]

When the input data is of type float32 and the environment variables MXNET_CUDA_ALLOW_TENSOR_CORE and MXNET_CUDA_TENSOR_OP_MATH_ALLOW_CONVERSION are set to 1, this operator will try to use pseudo-float16 precision (float32 math with float16 I/O) precision in order to use Tensor Cores on suitable NVIDIA GPUs. This can sometimes give significant speedups.

.. note:: The operator supports float32 and float64 data types only.
Examples::

Single matrix multiply-add

A = [[1.0, 1.0], [1.0, 1.0]]
B = [[1.0, 1.0], [1.0, 1.0], [1.0, 1.0]]
C =
[[1.0, 1.0, 1.0], [1.0, 1.0, 1.0]]
gemm(A, B, C, transpose_b=True, alpha=2.0, beta=10.0) =
[[14.0, 14.0, 14.0], [14.0, 14.0, 14.0]]

Batch matrix multiply-add

A = [[[[1.0, 1.0]], [[0.1, 0.1]]]]
B = [[[1.0, 1.0]], [[0.1, 0.1]]]
C = [[[10.0]], [[0.01]]]
gemm(A, B, C, transpose_b=True, alpha=2.0, beta=10.0) =
[[[104.0]], [[0.14]]]

Defined in src/operator/tensor/la_op.cc:L89

Value

out The result mx.symbol
For a non-default axis parameter, the operation performed is equivalent to a series of swapaxes/gemm/swapaxes calls. For example let *A*, *B* be 5 dimensional tensors. Then gemm(*A*, *B*, axis=1) is equivalent to the following without the overhead of the additional swapaxis operations::

\[
A1 = \text{swapaxes}(A, \text{dim1}=1, \text{dim2}=3) \quad B1 = \text{swapaxes}(B, \text{dim1}=1, \text{dim2}=3) \quad C = \text{gemm2}(A1, B1) \quad C = \text{swapaxis}(C, \text{dim1}=1, \text{dim2}=3)
\]

When the input data is of type float32 and the environment variables MXNET_CUDA_ALLOW_TENSOR_CORE and MXNET_CUDA_TENSOR_OP_MATH_ALLOW_CONVERSION are set to 1, this operator will try to use pseudo-float16 precision (float32 math with float16 I/O) precision in order to use Tensor Cores on suitable NVIDIA GPUs. This can sometimes give significant speedups.

.. note:: The operator supports float32 and float64 data types only.

Examples::

Single matrix multiply
\[
A = \begin{bmatrix} 1.0 & 1.0 \\ 1.0 & 1.0 \end{bmatrix} \quad B = \begin{bmatrix} 1.0 & 1.0 \\ 1.0 & 1.0 & 1.0 \end{bmatrix}
\]

\[
gemm2(A, B, \text{transpose_b}=\text{True}, \alpha=2.0) = \begin{bmatrix} 4.0 & 4.0 & 4.0 \\ 4.0 & 4.0 & 4.0 \end{bmatrix}
\]

Batch matrix multiply
\[
A = \begin{bmatrix} 1.0 & 1.0 \\ 0.1 & 0.1 \end{bmatrix} \quad B = \begin{bmatrix} 1.0 & 1.0 \\ 0.1 & 0.1 \end{bmatrix}
\]

\[
gemm2(A, B, \text{transpose_b}=\text{True}, \alpha=2.0) = \begin{bmatrix} 4.0 \\ 0.04 \end{bmatrix}
\]

Defined in src/operator/tensor/la_op.cc:L163

mx.symbol.linalg_makediag

.. linalg_makediag:: Constructs a square matrix with the input as diagonal. Input is a tensor \( \text{A} \) of dimension \( n \geq 1 \).

Description

If \( n=1 \), then \( \text{A} \) represents the diagonal entries of a single square matrix. This matrix will be returned as a 2-dimensional tensor. If \( n>1 \), then \( \text{A} \) represents a batch of diagonals of square matrices. The batch of diagonal matrices will be returned as an \( n+1 \)-dimensional tensor.

Usage

mx.symbol.linalg_makediag(...)
mx.symbol.linalg_maketrian

...linalg_maketrian: Constructs a square matrix with the input representing a specific triangular sub-matrix. This is basically the inverse of *linalg.extracttrian*. Input is a tensor *A* of dimension *n >= 1*.

Details

.. note:: The operator supports float32 and float64 data types only.

Examples::

Single diagonal matrix construction
A = [1.0, 2.0]

makediag(A) = [[1.0, 0.0], [0.0, 2.0]]

makediag(A, 1) = [[0.0, 1.0, 0.0], [0.0, 0.0, 2.0], [0.0, 0.0, 0.0]]

Batch diagonal matrix construction
A = [[1.0, 2.0], [3.0, 4.0]]

makediag(A) = [[[1.0, 0.0], [0.0, 2.0]], [[3.0, 0.0], [0.0, 4.0]]]

Defined in src/operator/tensor/la_op.cc:L547

Value

out The result mx.symbol

Description

If *n=1*, then *A* represents the entries of a triangular matrix which is lower triangular if *offset<0* or *offset=0*, *lower=true*. The resulting matrix is derived by first constructing the square matrix with the entries outside the triangle set to zero and then adding *offset*-times an additional diagonal with zero entries to the square matrix.

Usage

mx.symbol.linalg_maketrian(...)

Arguments

A
NDArray-or-Symbol Tensor of triangular matrices stored as vectors

offset
int, optional, default='0' Offset of the diagonal versus the main diagonal. 0 corresponds to the main diagonal, a negative/positive value to diagonals below/above the main diagonal.

lower
boolean, optional, default=1 Refer to the lower triangular matrix if lower=true, refer to the upper otherwise. Only relevant when offset=0

name
string, optional Name of the resulting symbol.
Details

If *n>1*, then *A* represents a batch of triangular sub-matrices. The batch of corresponding square matrices is returned as an *n+1* dimensional tensor.

.. note:: The operator supports float32 and float64 data types only.

Examples::

Single matrix construction A = [1.0, 2.0, 3.0]
maketrian(A) = [[1.0, 0.0], [2.0, 3.0]]
maketrian(A, lower=false) = [[1.0, 2.0], [0.0, 3.0]]
maketrian(A, offset=1) = [[0.0, 1.0, 2.0], [0.0, 0.0, 3.0], [0.0, 0.0, 0.0]] maketrian(A, offset=-1) =
[0.0, 0.0, 0.0], [1.0, 0.0, 0.0], [2.0, 3.0, 0.0]]

Batch matrix construction A = [[1.0, 2.0, 3.0], [4.0, 5.0, 6.0]]
maketrian(A) = [[[[1.0, 0.0], [2.0, 3.0]], [[4.0, 0.0], [5.0, 6.0]]]
maketrian(A, offset=1) = [[[0.0, 1.0, 2.0], [0.0, 0.0, 3.0], [0.0, 0.0, 0.0]], [[0.0, 4.0, 5.0], [0.0, 0.0, 6.0], [0.0, 0.0, 0.0]]]

Defined in src/operator/tensor/la_op.cc:L673

Value

out The result mx.symbol
mx.symbol.linalg_potri

Details

\(^A^* = A_{\text{tri}}^T \cdot A_{\text{tri}}^{-1}\) if \(\text{lower} = \text{true}\)
\(^A^* = A_{\text{tri}}^{-1} \cdot A_{\text{tri}}^T\) if \(\text{lower} = \text{false}\)

If \(n=2\), *potrf* is performed separately on the trailing two dimensions for all inputs (batch mode).

.. note:: The operator supports float32 and float64 data types only.

Examples::

Single matrix factorization \(A = \begin{bmatrix} 4.0 & 1.0 \\ 1.0 & 4.25 \end{bmatrix}\)
*potrf*(\(A\)) = \(\begin{bmatrix} 2.0 & 0 \\ 0.5 & 2.0 \end{bmatrix}\)

Batch matrix factorization \(A = \begin{bmatrix} \begin{bmatrix} 4.0 & 1.0 \\ 1.0 & 4.25 \end{bmatrix}, \begin{bmatrix} 16.0 & 4.0 \\ 4.0 & 17.0 \end{bmatrix} \end{bmatrix}\)
*potrf*(\(A\)) = \(\begin{bmatrix} \begin{bmatrix} 2.0 \\ 0 \end{bmatrix}, \begin{bmatrix} 4.0 \\ 1.0 \end{bmatrix} \end{bmatrix}\)

Defined in src/operator/tensor/la_op.cc:L214

Value

out The result mx.symbol

mx.symbol.linalg_potri

*linalg_potri*: Performs matrix inversion from a Cholesky factorization.

*Input is a tensor *A* of dimension *n >= 2*.

Description

If \(n=2\), *A* is a triangular matrix (entries of upper or lower triangle are all zero) with positive diagonal. We compute:

Usage

mx.symbol.linalg_potri(...)

Arguments

A

NDArray-or-Symbol Tensor of lower triangular matrices

name

string, optional Name of the resulting symbol.

Details

\(^\text{out}^* = A^* \cdot A^*\) if \(\text{lower} = \text{true}\)
\(^\text{out}^* = A^* \cdot A^*\) if \(\text{lower} = \text{false}\)

In other words, if \(A^*\) is the Cholesky factor of a symmetric positive definite matrix \(B^*\) (obtained by *potrf*), then
\(^\text{out}^* = B^*\) if \(\text{lower} = \text{false}\)

If \(n>2\), *potri* is performed separately on the trailing two dimensions for all inputs (batch mode).

.. note:: The operator supports float32 and float64 data types only.
.. note:: Use this operator only if you are certain you need the inverse of \(B\), and cannot use the Cholesky factor \(A\) (\(\text{potrf}\)), together with backsubstitution (\(\text{trsm}\)). The latter is numerically much safer, and also cheaper.

Examples::

Single matrix inverse \(A = \begin{bmatrix} 2.0, 0 \end{bmatrix}, \begin{bmatrix} 0.5, 2.0 \end{bmatrix}\) \(\text{potri}(A) = \begin{bmatrix} 0.26563, -0.0625 \end{bmatrix}, \begin{bmatrix} -0.0625, 0.25 \end{bmatrix}\)

Batch matrix inverse \(A = \begin{bmatrix} \begin{bmatrix} 2.0, 0 \end{bmatrix}, \begin{bmatrix} 0.5, 2.0 \end{bmatrix} \end{bmatrix}, \begin{bmatrix} 4.0, 0 \end{bmatrix}, \begin{bmatrix} 1.0, 4.0 \end{bmatrix} \) \(\text{potri}(A) = \begin{bmatrix} \begin{bmatrix} 0.26563, -0.0625 \end{bmatrix}, \begin{bmatrix} -0.0625, 0.25 \end{bmatrix} \end{bmatrix}, \begin{bmatrix} \begin{bmatrix} 0.06641, -0.01562 \end{bmatrix}, \begin{bmatrix} -0.01562, 0.0625 \end{bmatrix} \end{bmatrix}\)

Defined in src/operator/tensor/la_op.cc:L275

mx.symbol.linalg_syrk

**Description**

If *n=2*, the operator performs the BLAS3 function *syrk*:

**Usage**

mx.symbol.linalg_syrk(...)

**Arguments**

- **A** – NDArray-or-Symbol Tensor of input matrices
- **transpose** – boolean, optional, default=0 Use transpose of input matrix.
- **alpha** – double, optional, default=1 Scalar factor to be applied to the result.
- **name** – string, optional Name of the resulting symbol.

**Details**

\[ *\text{out} = \alpha \cdot A \cdot A^T \]

if *transpose=False*, or
\[ *\text{out} = \alpha \cdot A^T \cdot A *\]

if *transpose=True*.

If *n>2*, *syrk* is performed separately on the trailing two dimensions for all inputs (batch mode).

.. note:: The operator supports float32 and float64 data types only.

**Examples**:

Single matrix multiply
\[ A = \begin{bmatrix} 1. & 2. \\ 4. & 5. \end{bmatrix} \]
\[ \text{syrk}(A, \alpha=1., \text{transpose}=\text{False}) = \begin{bmatrix} 14. & 32. \\ 32. & 77. \end{bmatrix} \]
\[ \text{syrk}(A, \alpha=1., \text{transpose}=\text{True}) = \begin{bmatrix} 17. & 22. & 27. \\ 22. & 29. & 36. \\ 27. & 36. & 45. \end{bmatrix} \]

Batch matrix multiply
\[ A = \begin{bmatrix} 1. & 1. \\ 0.1 & 0.1 \end{bmatrix} \]
\[ \text{syrk}(A, \alpha=2., \text{transpose}=\text{False}) = \begin{bmatrix} 4. \\ 0.04 \end{bmatrix} \]

Defined in src/operator/tensor/la_op.cc:L730

**Value**

out The result mx.symbol
mx.symbol.linalg_trmm

```
linalg_trmm: Performs multiplication with a lower triangular matrix.
Input are tensors *A*, *B*, each of dimension *n >= 2* and having
the same shape on the leading *n-2* dimensions.
```

**Description**

If *n=2*, *A* must be triangular. The operator performs the BLAS3 function *trmm*:

**Usage**

```
mx.symbol.linalg_trmm(...)  
```

**Arguments**

- **A**: NDArray-or-Symbol Tensor of lower triangular matrices
- **B**: NDArray-or-Symbol Tensor of matrices
- **transpose**: boolean, optional, default=0 Use transposed of the triangular matrix
- **rightside**: boolean, optional, default=0 Multiply triangular matrix from the right to non-
  triangular one.
- **lower**: boolean, optional, default=1 True if the triangular matrix is lower triangular,
  false if it is upper triangular.
- **alpha**: double, optional, default=1 Scalar factor to be applied to the result.
- **name**: string, optional Name of the resulting symbol.

**Details**

*out* = *alpha* \* *op*(*A*) \* *B*

if *rightside=False*, or

*out* = (*alpha* \* *B*) \* *op*(*A*)

if *rightside=True*. Here, *alpha* is a scalar parameter, and *op()* is either the identity or the
matrix transposition (depending on *transpose*).

If *n>2*, *trmm* is performed separately on the trailing two dimensions for all inputs (batch mode).

.. note:: The operator supports float32 and float64 data types only.

**Examples:**

Single triangular matrix multiply

A = [[1.0, 0], [1.0, 1.0]]  
B = [[1.0, 1.0, 1.0], [1.0, 1.0, 1.0]]  
trmm(A, B, alpha=2.0) = [[2.0, 2.0, 2.0], [4.0, 4.0, 4.0]]

Batch triangular matrix multiply

A = [[[1.0, 0], [1.0, 1.0]], [[1.0, 0], [1.0, 1.0]]]  
B = [[[1.0, 1.0, 1.0], [1.0, 1.0, 1.0]], [[0.5, 0.5, 0.5], [0.5, 0.5, 0.5]]]  
trmm(A, B, alpha=2.0) = [[[2.0, 2.0, 2.0], [4.0, 4.0, 4.0]], [[1.0, 1.0, 1.0], [2.0, 2.0, 2.0]]]

Defined in src/operator/tensor/la_op.cc:L333
mx.symbol.linalg_trsm

linalg_trsm:Solves matrix equation involving a lower triangular matrix. Input are tensors *A*, *B*, each of dimension *n >= 2* and having the same shape on the leading *n-2* dimensions.

Description

If *n=2*, *A* must be triangular. The operator performs the BLAS3 function *trsm*, solving for *out* in:

Usage

mx.symbol.linalg_trsm(...)

Arguments

- **A**: NDArray-or-Symbol Tensor of lower triangular matrices
- **B**: NDArray-or-Symbol Tensor of matrices
- **transpose**: boolean, optional, default=0 Use transposed of the triangular matrix
- **rightside**: boolean, optional, default=0 Multiply triangular matrix from the right to non-triangular one.
- **lower**: boolean, optional, default=1 True if the triangular matrix is lower triangular, false if it is upper triangular.
- **alpha**: double, optional, default=1 Scalar factor to be applied to the result.
- **name**: string, optional Name of the resulting symbol.

Details

*op*(\(\mathbf{A}\)) \* *out* = *alpha* \* *B*
if *rightside=False*, or

*out* \* *op*(\(\mathbf{A}\)) = *alpha* \* *B*
if *rightside=True*. Here, *alpha* is a scalar parameter, and *op()* is either the identity or the matrix transposition (depending on *transpose*).

If *n>2*, *trsm* is performed separately on the trailing two dimensions for all inputs (batch mode).

Examples:

Single matrix solve A = \([[[1.0, 0], [1.0, 0]], [2.0, 2.0, 2.0], [4.0, 4.0, 4.0]]\) B = \([[1.0, 0], [1.0, 0], [2.0, 2.0, 2.0], [4.0, 4.0, 4.0]]\) trsm(A, B, alpha=0.5) = \([[1.0, 1.0, 1.0], [1.0, 1.0, 1.0], [1.0, 1.0, 1.0]]\)

Batch matrix solve A = \([[[[1.0, 0], [1.0, 0]], [1.0, 1.0]], [2.0, 2.0, 2.0], [4.0, 4.0, 4.0]]\) B = \([[[[1.0, 0], [1.0, 0]], [1.0, 1.0]], [2.0, 2.0, 2.0], [4.0, 4.0, 4.0]]\) trsm(A, B, alpha=0.5) = \([[[[1.0, 1.0, 1.0], [1.0, 1.0, 1.0]], [1.0, 1.0, 1.0]]\), [[2.0, 2.0, 2.0], [2.0, 2.0, 2.0]]\)

Defined in src/operator/tensor/la_op.cc:L396
mx.symbol.LinearRegressionOutput

LinearRegressionOutput: Computes and optimizes for squared loss during backward propagation. Just outputs “data” during forward propagation.

Description

If \( \hat{y}_i \) is the predicted value of the \( i \)-th sample, and \( y_i \) is the corresponding target value, then the squared loss estimated over \( n \) samples is defined as

\[
\text{SquaredLoss}(\textbf{Y}, \hat{\textbf{Y}}) = \frac{1}{n} \sum_{i=0}^{n-1} \| \textbf{y}_i - \hat{\textbf{y}}_i \|_2^2
\]

.. note:: Use the LinearRegressionOutput as the final output layer of a net.

The storage type of “label” can be “default” or “csr”

- LinearRegressionOutput(default, default) = default - LinearRegressionOutput(default, csr) = default

By default, gradients of this loss function are scaled by factor ‘1/m’, where \( m \) is the number of regression outputs of a training example. The parameter ‘grad_scale’ can be used to change this scale to ‘grad_scale/m’.

Defined in src/operator/regression_output.cc:L92

Value

out The result mx.symbol
mx.symbol.load

Load an mx.symbol object

Description
Load an mx.symbol object

Usage
mx.symbol.load(file.name)

Arguments
filename the filename (including the path)

Examples
```
data = mx.symbol.Variable('data')
mx.symbol.save(data, 'temp.symbol')
data2 = mx.symbol.load('temp.symbol')
```

mx.symbol.load.json

Load an mx.symbol object from a json string

Description
Load an mx.symbol object from a json string

Arguments
str the json str represent a mx.symbol
mx.symbol.log

log: Returns element-wise Natural logarithmic value of the input.

Description
The natural logarithm is logarithm in base *e*, so that “log(exp(x)) = x“

Usage
mx.symbol.log(...)

Arguments
- data: NDArray-or-Symbol The input array.
- name: string, optional Name of the resulting symbol.

Details
The storage type of “log“ output is always dense
Defined in src/operator/tensor/elemwise_unary_op_logexp.cc:L77

Value
out: The result mx.symbol

mx.symbol.log10

log10: Returns element-wise Base-10 logarithmic value of the input.

Description
“10**log10(x) = x“

Usage
mx.symbol.log10(...)

Arguments
- data: NDArray-or-Symbol The input array.
- name: string, optional Name of the resulting symbol.

Details
The storage type of “log10“ output is always dense
Defined in src/operator/tensor/elemwise_unary_op_logexp.cc:L94
**Value**

out The result mx.symbol

---

**mx.symbol.log1p**  

*log1p*: Returns element-wise “log(1 + x)" value of the input.

---

**Description**

This function is more accurate than “log(1 + x)“ for small “x" so that :math:`1+x\approx 1`

**Usage**

`mx.symbol.log1p(...)`

**Arguments**

- **data**: NDArray-or-Symbol The input array.
- **name**: string, optional Name of the resulting symbol.

**Details**

The storage type of “log1p” output depends upon the input storage type:

- log1p(default) = default - log1p(row_sparse) = row_sparse - log1p(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_logexp.cc:L199

---

**Value**

out The result mx.symbol

---

**mx.symbol.log2**  

*log2*: Returns element-wise Base-2 logarithmic value of the input.

---

**Description**

“2**log2(x) = x“

**Usage**

`mx.symbol.log2(...)`

**Arguments**

- **data**: NDArray-or-Symbol The input array.
- **name**: string, optional Name of the resulting symbol.
Details

The storage type of “log2“ output is always dense
Defined in src/operator/tensor/ElemwiseUnaryOpLogexp.cc:L106

Value

out The result mx.symbol

mx.symbol.logical_not  logical_not:Returns the result of logical NOT (!) function

Description

Example: logical_not([-2., 0., 1.]) = [0., 1., 0.]

Usage

mx.symbol.logical_not(...)

Arguments

data NDArray-or-Symbol The input array.
name string, optional Name of the resulting symbol.

Value

out The result mx.symbol

mx.symbol.LogisticRegressionOutput

LogisticRegressionOutput:Applies a logistic function to the input.

Description

The logistic function, also known as the sigmoid function, is computed as :math:`\frac{1}{1+\exp(-\text{bf{x}})}`.

Usage

mx.symbol.LogisticRegressionOutput(...)
Arguments

- **data**: NDArray-or-Symbol Input data to the function.
- **label**: NDArray-or-Symbol Input label to the function.
- **grad.scale**: float, optional, default=1 Scale the gradient by a float factor
- **name**: string, optional Name of the resulting symbol.

Details

Commonly, the sigmoid is used to squash the real-valued output of a linear model $w^T x + b$ into the $[0, 1]$ range so that it can be interpreted as a probability. It is suitable for binary classification or probability prediction tasks.

.. note:: Use the LogisticRegressionOutput as the final output layer of a net.

The storage type of “label“ can be “default“ or “csr“

- LogisticRegressionOutput(default, default) = default
- LogisticRegressionOutput(default, csr) = default

The loss function used is the Binary Cross Entropy Loss:

$$-(y \log(p) + (1 - y) \log(1 - p))$$

Where ‘y’ is the ground truth probability of positive outcome for a given example, and ‘p’ the probability predicted by the model. By default, gradients of this loss function are scaled by factor ‘1/m’, where m is the number of regression outputs of a training example. The parameter ‘grad_scale’ can be used to change this scale to ‘grad_scale/m’.

Defined in src/operator/regression_output.cc:L152

Value

- out The result mx.symbol

mx.symbol.log_softmax  

log_softmax: Computes the log softmax of the input. This is equivalent to computing softmax followed by log.

Description

Examples::

Usage

mx.symbol.log_softmax(...)
mx.symbol.LRN

**Arguments**

- **data**: NDArray-or-Symbol The input array.
- **axis**: int, optional, default='-1' The axis along which to compute softmax.
- **temperature**: double or None, optional, default=None Temperature parameter in softmax
- **dtype**: None, 'float16', 'float32', 'float64', optional, default=None DTtype of the output in case this can’t be inferred. Defaults to the same as input’s dtype if not defined (dtype=None).
- **use.length**: boolean or None, optional, default=0 Whether to use the length input as a mask over the data input.
- **name**: string, optional Name of the resulting symbol.

**Details**

```python
>>> x = mx.nd.array([1, 2, 1])
>>> mx.nd.log_softmax(x).asnumpy()
array([-1.41702998, -0.41702995, -2.31702995], dtype=float32)
```

```python
>>> x = mx.nd.array([[1, 2, 1], [1, 2, 1]])
>>> mx.nd.log_softmax(x, axis=0).asnumpy()
array([[-0.34115392, -0.69314718, -1.24115396],
       [-1.24115396, -0.69314718, -0.34115392]], dtype=float32)
```

**Value**

- **out**: The result mx.symbol

---

mx.symbol.LRN

**LRN**: Applies local response normalization to the input.

**Description**

The local response normalization layer performs "lateral inhibition" by normalizing over local input regions.

**Usage**

- `mx.symbol.LRN(...)`

**Arguments**

- **data**: NDArray-or-Symbol Input data to LRN
- **alpha**: float, optional, default=9.99999975e-05 The variance scaling parameter \( \alpha \) in the LRN expression.
- **beta**: float, optional, default=0.75 The power parameter \( \beta \) in the LRN expression.
- **knorm**: float, optional, default=2 The parameter \( k \) in the LRN expression.
- **nsize**: int (non-negative), required normalization window width in elements.
- **name**: string, optional Name of the resulting symbol.
mx.symbol.MAERegressionOutput

Details

If \( a_{x,y}^i \) is the activity of a neuron computed by applying kernel \( i \) at position \( (x, y) \) and then applying the ReLU nonlinearity, the response-normalized activity \( b_{x,y}^i \) is given by the expression:

\[
b_{x,y}^i = \frac{a_{x,y}^i}{k + \frac{n}{\alpha} \sum_{j=\max(0, i-\frac{n}{2})}^{\min(N-1, i+\frac{n}{2})} (a_{x,y}^j)^2} \quad \beta
\]

where the sum runs over \( n \) "adjacent" kernel maps at the same spatial position, and \( N \) is the total number of kernels in the layer.

Defined in src/operator/nn/lrn.cc:L158

Value

out The result mx.symbol

mx.symbol.MAERegressionOutput

MAERegressionOutput: Computes mean absolute error of the input.

Description

MAE is a risk metric corresponding to the expected value of the absolute error.

Usage

mx.symbol.MAERegressionOutput(...)

Arguments

data NDArray-or-Symbol Input data to the function.

label NDArray-or-Symbol Input label to the function.

grad.scale float, optional, default=1 Scale the gradient by a float factor

name string, optional Name of the resulting symbol.

Details

If \( \hat{y}_i \) is the predicted value of the \( i \)-th sample, and \( y_i \) is the corresponding target value, then the mean absolute error (MAE) estimated over \( n \) samples is defined as

\[
\text{MAE}(\textbf{Y}, \hat{\textbf{Y}}) = \frac{1}{n} \sum_{i=0}^{n-1} |y_i - \hat{y}_i|
\]

.. note:: Use the MAERegressionOutput as the final output layer of a net.

The storage type of “label” can be “default” or “csr”

- MAERegressionOutput(default, default) = default - MAERegressionOutput(default, csr) = default

By default, gradients of this loss function are scaled by factor \( 1/m \), where \( m \) is the number of regression outputs of a training example. The parameter \( \text{grad.scale} \) can be used to change this scale to \( \text{grad.scale}/m \).

Defined in src/operator/regression_output.cc:L120
**Value**

out The result mx.symbol

---

**mx.symbol.MakeLoss**

*MakeLoss*: Make your own loss function in network construction.

**Description**

This operator accepts a customized loss function symbol as a terminal loss and the symbol should be an operator with no backward dependency. The output of this function is the gradient of loss with respect to the input data.

**Usage**

mx.symbol.MakeLoss(...)  

**Arguments**

- **data**: NDArray-or-Symbol Input array.
- **grad.scale**: float, optional, default=1 Gradient scale as a supplement to unary and binary operators
- **valid.thresh**: float, optional, default=0 clip each element in the array to 0 when it is less than “valid.thresh”. This is used when “normalization” is set to “’valid’”.
- **normalization**: ‘batch’, ‘null’, ‘valid’.optional, default=’null’ If this is set to null, the output gradient will not be normalized. If this is set to batch, the output gradient will be divided by the batch size. If this is set to valid, the output gradient will be divided by the number of valid input elements.
- **name**: string, optional Name of the resulting symbol.

**Details**

For example, if you are making a cross entropy loss function. Assume “out” is the predicted output and “label” is the true label, then the cross entropy can be defined as:

cross_entropy = label * log(out) + (1 - label) * log(1 - out)  
loss = MakeLoss(cross_entropy)

We will need to use “MakeLoss” when we are creating our own loss function or we want to combine multiple loss functions. Also we may want to stop some variables’ gradients from backpropagation. See more detail in “BlockGrad” or “stop_gradient”.

In addition, we can give a scale to the loss by setting “grad_scale”, so that the gradient of the loss will be rescaled in the backpropagation.

.. note:: This operator should be used as a Symbol instead of NDArray.

Defined in src/operator/make_loss.cc:L71

**Value**

out The result mx.symbol
**mx.symbol.make_loss**

*make_loss*: Make your own loss function in network construction.

**Description**

This operator accepts a customized loss function symbol as a terminal loss and the symbol should be an operator with no backward dependency. The output of this function is the gradient of loss with respect to the input data.

**Usage**

```python
mx.symbol.make_loss(...)```

**Arguments**

- `data` NDArray-or-Symbol: The input array.
- `name` string, optional: Name of the resulting symbol.

**Details**

For example, if you are making a cross entropy loss function. Assume “out” is the predicted output and “label” is the true label, then the cross entropy can be defined as:

```python
cross_entropy = label * log(out) + (1 - label) * log(1 - out) loss = make_loss(cross_entropy)
```

We will need to use “make_loss” when we are creating our own loss function or we want to combine multiple loss functions. Also we may want to stop some variables’ gradients from backpropagation. See more detail in “BlockGrad” or “stop_gradient”.

The storage type of “make_loss” output depends upon the input storage type:

- `make_loss(default) = default`
- `make_loss(row_sparse) = row_sparse`

Defined in `src/operator/tensor/elemwise_unary_op_basic.cc:L358`

**Value**

```
out The result mx.symbol
```

**mx.symbol.max**

*max*: Computes the max of array elements over given axes.

**Description**

Defined in `src/operator/tensor/./broadcast_reduce_op.h:L32`

**Usage**

```python
mx.symbol.max(...)```
mx.symbol.max_axis

Arguments

- **data**: NDArray-or-Symbol The input.
- **axis**: Shape or None, optional, default=None The axis or axes along which to perform the reduction.
  - The default, `axis=()`, will compute over all elements into a scalar array with shape `(1,)`.
  - If `axis` is int, a reduction is performed on a particular axis.
  - If `axis` is a tuple of ints, a reduction is performed on all the axes specified in the tuple.
  - If `exclude` is true, reduction will be performed on the axes that are NOT in axis instead.
  - Negative values means indexing from right to left.
- **keepdims**: boolean, optional, default=0 If this is set to ‘True’, the reduced axes are left in the result as dimension with size one.
- **exclude**: boolean, optional, default=0 Whether to perform reduction on axis that are NOT in axis instead.
- **name**: string, optional Name of the resulting symbol.

Value

- **out**: The result mx.symbol

mx.symbol.max_axis

max_axis:Computes the max of array elements over given axes.

Description

Defined in src/operator/tensor/./broadcast_reduce_op.h:L32

Usage

mx.symbol.max_axis(...)
mx.symbol.mean

keepdims boolean, optional, default=0 If this is set to ‘True’, the reduced axes are left in the result as dimension with size one.

exclude boolean, optional, default=0 Whether to perform reduction on axis that are NOT in axis instead.

name string, optional Name of the resulting symbol.

Value

out The result mx.symbol

mx.symbol.mean mean: Computes the mean of array elements over given axes.

Description

Defined in src/operator/tensor/./broadcast_reduce_op.h:L84

Usage

mx.symbol.mean(...)
mx.symbol.moments

moments: Calculate the mean and variance of 'data'.

Description

The mean and variance are calculated by aggregating the contents of data across axes. If x is 1-D and axes = [0] this is just the mean and variance of a vector.

Usage

mx.symbol.moments(...)  

Arguments

data: NDArray-or-Symbol Input ndarray
axes: Shape or None, optional, default=None Array of ints. Axes along which to compute mean and variance.
keepdims: boolean, optional, default=0 produce moments with the same dimensionality as the input.
name: string, optional Name of the resulting symbol.

Details

Example:

x = [[1, 2, 3], [4, 5, 6]] mean, var = moments(data=x, axes=[0]) mean = [2.5, 3.5, 4.5] var = [2.25, 2.25, 2.25] mean, var = moments(data=x, axes=[1]) mean = [2.0, 5.0] var = [0.66666667, 0.66666667] mean, var = moments(data=x, axis=[0, 1]) mean = [3.5] var = [2.9166667]

Defined in src/operator/nn/moments.cc:L54

Value

out The result mx.symbol

mx.symbol.mp_lamb_update_phase1

mp_lamb_update_phase1: Mixed Precision version of Phase I of lamb update it performs the following operations and returns g:

Description

Usage

mx.symbol.mp_lamb_update_phase1(...)

Arguments

- **weight**: NDArray-or-Symbol Weight
- **grad**: NDArray-or-Symbol Gradient
- **mean**: NDArray-or-Symbol Moving mean
- **var**: NDArray-or-Symbol Moving variance
- **weight32**: NDArray-or-Symbol Weight32
- **beta1**: float, optional, default=0.899999976 The decay rate for the 1st moment estimates.
- **beta2**: float, optional, default=0.999000013 The decay rate for the 2nd moment estimates.
- **epsilon**: float, optional, default=9.99999997e-07 A small constant for numerical stability.
- **t**: int, required Index update count.
- **bias.correction**: boolean, optional, default=1 Whether to use bias correction.
- **wd**: float, required Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
- **rescale.grad**: float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
- **clip.gradient**: float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient] If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).
- **name**: string, optional Name of the resulting symbol.

Details

.. math:: 
\begin{gather*}
\text{grad32} = \text{grad(float16)} \times \text{rescale\_grad}\text{ if } (\text{grad} < -\text{clip}\_\text{gradient}) \text{ then } \text{grad} = -\text{clip}\_\text{gradient}\text{ if } (\text{grad} > \text{clip}\_\text{gradient}) \text{ then } \text{grad} = \text{clip}\_\text{gradient}
\end{gather*}

\begin{align*}
\text{mean} &= \text{beta1} \times \text{mean} + (1 - \text{beta1}) \times \text{grad}; \text{variance} = \text{beta2} \times \text{variance} + (1 - \text{beta2}) \times \text{grad}^2;
\text{if } (\text{bias\_correction}) \text{ then } \text{mean\_hat} = \text{mean} / (1 - \text{beta1}^\text{t}); \text{var\_hat} = \text{var} / (1 - \text{beta2}^\text{t}); \text{g} = \text{mean\_hat} / (\text{var\_hat}^{(1/2) + \text{epsilon}}) + \text{wd} \times \text{weight32}; \text{else } \text{g} = \text{mean} / (\text{var\_data}^{(1/2) + \text{epsilon}}) + \text{wd} \times \text{weight32};
\end{align*}

Defined in src/operator/optimizer_op.cc:L1033

Value

- **out**: The result mx.symbol
mx.symbol.mp_lamb_update_phase2

**mp_lamb_update_phase2**: Mixed Precision version Phase II of lamb update. It performs the following operations and updates grad.

### Description

### Usage

```python
mx.symbol.mp_lamb_update_phase2(...)
```

### Arguments

- **weight**: NDArray-or-Symbol Weight
- **g**: NDArray-or-Symbol Output of mp_lamb_update_phase 1
- **r1**: NDArray-or-Symbol r1
- **r2**: NDArray-or-Symbol r2
- **weight32**: NDArray-or-Symbol Weight32
- **lr**: float, required Learning rate
- **lower.bound**: float, optional, default=-1 Lower limit of norm of weight. If lower_bound <= 0, Lower limit is not set
- **upper.bound**: float, optional, default=-1 Upper limit of norm of weight. If upper_bound <= 0, Upper limit is not set
- **name**: string, optional Name of the resulting symbol.

### Details

```
.. math::
\begin{align*}
  & \text{if (lower_bound} \geq 0) \text{ then r1 = max(r1, lower_bound) if (upper_bound} \geq 0) \text{ then r1 = max(r1, upper_bound)} \\
  & \text{if (r1 == 0 or r2 == 0) then lr = lr else lr = lr * (r1/r2) weight32 = weight32 - lr * g weight(float16)} \\
  & \text{weight32}
\end{align*}
```

Defined in src/operator/optimizer_op.cc:L1075

### Value

- **out**: The result mx.symbol
Description

Defined in src/operator/optimizer_op.cc:L745

Usage

mx.symbol.mp_nag_mom_update(...)

Arguments

- **weight**: NDArray-or-Symbol Weight
- **grad**: NDArray-or-Symbol Gradient
- **mom**: NDArray-or-Symbol Momentum
- **weight32**: NDArray-or-Symbol Weight32
- **lr**: float, required Learning rate
- **momentum**: float, optional, default=0 The decay rate of momentum estimates at each epoch.
- **wd**: float, optional, default=0 Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
- **rescale.grad**: float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
- **clip.gradient**: float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient] If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).
- **name**: string, optional Name of the resulting symbol.

Value

- **out**: The result mx.symbol
mx.symbol.mp_sgd_mom_update

mp_sgd_mom_update: Updater function for multi-precision sgd optimizer

Description

mp_sgd_mom_update: Updater function for multi-precision sgd optimizer

Usage

mx.symbol.mp_sgd_mom_update(...)

Arguments

weight: NDArray-or-Symbol Weight
grad: NDArray-or-Symbol Gradient
mom: NDArray-or-Symbol Momentum
weight32: NDArray-or-Symbol Weight32
lr: float, required Learning rate
momentum: float, optional, default=0 The decay rate of momentum estimates at each epoch.
wd: float, optional, default=0 Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
rescale.grad: float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
clip.gradient: float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient] If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).
lazy.update: boolean, optional, default=1 If true, lazy updates are applied if gradient’s stype is row_sparse and both weight and momentum have the same stype
name: string, optional Name of the resulting symbol.

Value

out: The result mx.symbol
mx.symbol.mp_sgd_update

mp_sgd_update: Updater function for multi-precision sgd optimizer

Description

mx.symbol.mp_sgd_update: Updater function for multi-precision sgd optimizer

Usage

mx.symbol.mp_sgd_update(...)

Arguments

weight  NDArray-or-Symbol Weight
grad    NDArray-or-Symbol gradient
weight32 NDArray-or-Symbol Weight32
lr      float, required Learning rate
wd      float, optional, default=0 Weight decay augments the objective function with a
        regularization term that penalizes large weights. The penalty scales with the
        square of the magnitude of each weight.
rescale.grad float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
clip.gradient float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient]
        If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad,
        clip_gradient), -clip_gradient).
lazy.update boolean, optional, default=1 If true, lazy updates are applied if gradient’s stype
        is row_sparse.
name    string, optional Name of the resulting symbol.

Value

out The result mx.symbol

mx.symbol.multi_all_finite

multi_all_finite: Check if all the float numbers in all the arrays are
finite (used for AMP)

Description

Defined in src/operator/contrib/all_finite.cc:L133
**Usage**

```python
mx.symbol.multi_all_finite(...)
```

**Arguments**

- `data` (NDArray-or-Symbol[]): Arrays
- `num.arrays` (int, optional, default='1') Number of arrays.
- `init.output` (boolean, optional, default=1) Initialize output to 1.
- `name` (string, optional) Name of the resulting symbol.

**Value**

```python
out The result mx.symbol
```

---

**mx.symbol.multi_lars**

`multi_lars`: Compute the LARS coefficients of multiple weights and grads from their sums of square

---

**Description**

Defined in `src/operator/contrib/multi_lars.cc:L37`

**Usage**

```python
mx.symbol.multi_lars(...)
```

**Arguments**

- `lrs` (NDArray-or-Symbol) Learning rates to scale by LARS coefficient
- `weights.sum.sq` (NDArray-or-Symbol) sum of square of weights arrays
- `grads.sum.sq` (NDArray-or-Symbol) sum of square of gradients arrays
- `wds` (NDArray-or-Symbol) weight decays
- `eta` (float, required) LARS eta
- `eps` (float, required) LARS eps
- `rescale.grad` (float, optional, default=1) Gradient rescaling factor
- `name` (string, optional) Name of the resulting symbol.

**Value**

```python
out The result mx.symbol
```
mx.symbol.multi_mp_sgd_mom_update

**multi_mp_sgd_mom_update:** Momentum update function for multi-precision Stochastic Gradient Descent (SGD) optimizer.

**Description**

Momentum update has better convergence rates on neural networks. Mathematically it looks like below:

**Usage**

```python
mx.symbol.multi_mp_sgd_mom_update(...)
```

**Arguments**

- **data**: NDArray-or-Symbol[] Weights
- **lrs**: tuple of <float>, required Learning rates.
- **wds**: tuple of <float>, required Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
- **momentum**: float, optional, default=0 The decay rate of momentum estimates at each epoch.
- **rescale.grad**: float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
- **clip.gradient**: float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient]. If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).
- **num.weights**: int, optional, default=`1` Number of updated weights.
- **name**: string, optional Name of the resulting symbol.

**Details**

.. math::

   v_1 = \alpha * \nabla J(W_0) \quad v_t = \gamma v_{t-1} - \alpha * \nabla J(W_{t-1}) \quad W_t = W_{t-1} + v_t

It updates the weights using::

v = momentum * v - learning_rate * gradient weight += v

Where the parameter “momentum” is the decay rate of momentum estimates at each epoch.

Defined in src/operator/optimizer_op.cc:L472

**Value**

- **out**: The result mx.symbol
**mx.symbol.multi_mp_sgd_update**

**multi_mp_sgd_update**: Update function for multi-precision Stochastic Gradient Descent (SDG) optimizer.

**Description**

It updates the weights using:

\[ weight = weight - learning_rate \times (gradient + wd \times weight) \]

**Usage**

mx.symbol.multi_mp_sgd_update(...)

**Arguments**

- **data**: NDArray-or-Symbol[] Weights
- **lrs**: tuple of <float>, required Learning rates.
- **wds**: tuple of <float>, required Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
- **rescale.grad**: float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
- **clip.gradient**: float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient] If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).
- **num.weights**: int, optional, default='1' Number of updated weights.
- **name**: string, optional Name of the resulting symbol.

**Details**

weight = weight - learning_rate \times (gradient + wd \times weight)

Defined in src/operator/optimizer_op.cc:L417

**Value**

out The result mx.symbol
multi_sgd_mom_update: Momentum update function for Stochastic Gradient Descent (SGD) optimizer.

Description

Momentum update has better convergence rates on neural networks. Mathematically it looks like below:

\[ v_1 = \alpha \nabla J(W_0) \]
\[ v_t = \gamma v_{t-1} - \alpha \nabla J(W_{t-1}) \]
\[ W_t = W_{t-1} + v_t \]

It updates the weights using:

\[ v = \text{momentum} \cdot v - \text{learning_rate} \cdot \text{gradient} \]
\[ weight += v \]

Where the parameter “momentum” is the decay rate of momentum estimates at each epoch.

Defined in src/operator/optimizer_op.cc:L374

Usage

mx.symbol.multi_sgd_mom_update(...)  

Arguments

- **data**: NDArray-or-Symbol[] Weights, gradients and momentum  
- **lrs**: tuple of <float>, required Learning rates.  
- **wds**: tuple of <float>, required Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.  
- **momentum**: float, optional, default=0 The decay rate of momentum estimates at each epoch.  
- **rescale.grad**: float, optional, default=1 Rescale gradient to \( \text{grad} = \text{rescale\_grad} \cdot \text{grad} \).  
- **clip.gradient**: float, optional, default=-1 Clip gradient to the range of \([-\text{clip\_gradient}, \text{clip\_gradient}]\) 
  
  If \( \text{clip\_gradient} \leq 0 \), gradient clipping is turned off. \( \text{grad} = \max(\min(\text{grad}, \text{clip\_gradient}), -\text{clip\_gradient}) \).  
- **num.weights**: int, optional, default='1' Number of updated weights.  
- **name**: string, optional Name of the resulting symbol.

Details

.. math::

\[ v_{t-1} = \alpha \nabla J(W_{t-1}) \]
\[ v_{t} = \gamma v_{t-1} - \alpha \nabla J(W_{t-1}) \]
\[ W_{t} = W_{t-1} + v_{t} \]

It updates the weights using:

\[ v = \alpha \nabla J(W_{t-1}) \]
\[ weight += v \]

Where the parameter “momentum” is the decay rate of momentum estimates at each epoch.

Defined in src/operator/optimizer_op.cc:L374

Value

out The result mx.symbol
**Description**

It updates the weights using:

**Usage**

```python
mx.symbol.multi_sgd_update(...)```

**Arguments**

- **data**: NDArray-or-Symbol[] Weights
- **lrs**: tuple of <float>, required Learning rates.
- **wds**: tuple of <float>, required Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
- **rescale.grad**: float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.

- **name**: string, optional Name of the resulting symbol.

**Details**

weight = weight - learning_rate * (gradient + wd * weight)

Defined in src/operator/optimizer_op.cc:L329

**Value**

```python
out The result mx.symbol```
**mx.symbol.multi_sum_sq**

*multi_sum_sq:* Compute the sums of squares of multiple arrays

---

**Description**

Defined in src/operator/contrib/multi_sum_sq.cc:L36

**Usage**

```python
mx.symbol.multi_sum_sq(...)```

**Arguments**

- **data**: NDArray-or-Symbol[] Arrays
- **num.arrays**: int, required number of input arrays.
- **name**: string, optional Name of the resulting symbol.

**Value**

```python
out The result mx.symbol
```

---

**mx.symbol.nag_mom_update**

*nag_mom_update:* Update function for Nesterov Accelerated Gradient (NAG) optimizer. It updates the weights using the following formula,

\[
\begin{align*}
  v_{t} &= \gamma v_{t-1} + \eta \nabla J(W_{t-1} - \gamma v_{t-1}) \\
  W_{t} &= W_{t-1} - v_{t}
\end{align*}
\]

---

**Description**

```
.. math:: v_{t} = \gamma v_{t-1} + \eta \nabla J(W_{t-1} - \gamma v_{t-1}) \\
W_{t} = W_{t-1} - v_{t}
```

**Usage**

```python
mx.symbol.nag_mom_update(...)```

**Arguments**

- **weight**: NDArray-or-Symbol Weight
- **grad**: NDArray-or-Symbol Gradient
- **mom**: NDArray-or-Symbol Momentum
- **lr**: float, required Learning rate
- **momentum**: float, optional, default=0 The decay rate of momentum estimates at each epoch.
**mx.symbol.nanprod**

float, optional, default=0 Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.

**rescale.grad** float, optional, default=1 Rescale gradient to \( \text{grad} = \text{rescale}\_\text{grad} \times \text{grad} \).

**clip.gradient** float, optional, default=-1 Clip gradient to the range of \([-\text{clip}\_\text{gradient}, \text{clip}\_\text{gradient}]\)
If \( \text{clip}\_\text{gradient} \leq 0 \), gradient clipping is turned off.
\( \text{grad} = \max(\min(\text{grad}, \text{clip}\_\text{gradient}), -\text{clip}\_\text{gradient}) \).

**name** string, optional Name of the resulting symbol.

**Details**
Where \( \eta \) is the learning rate of the optimizer, \( \gamma \) is the decay rate of the momentum estimate, \( \mathbf{v}_t \) is the update vector at time step 't', \( \mathbf{W}_t \) is the weight vector at time step 't'.
Defined in src/operator/optimizer_op.cc:L726

**Value**
out The result mx.symbol

---

**Description**
nanprod: Computes the product of array elements over given axes treating Not a Numbers ("NaN") as one.

**Usage**
mx.symbol.nanprod(...)
mx.symbol.nansum

keepdims boolean, optional, default=0 If this is set to ‘True’, the reduced axes are left in the result as dimension with size one.
exclude boolean, optional, default=0 Whether to perform reduction on axis that are NOT in axis instead.
name string, optional Name of the resulting symbol.

Details
Defined in src/operator/tensor/broadcast_reduce_prod_value.cc:L47

Value
out The result mx.symbol

mx.symbol.nansum

nansum: Computes the sum of array elements over given axes treating Not a Numbers (“NaN”) as zero.

Description
nansum: Computes the sum of array elements over given axes treating Not a Numbers (“NaN”) as zero.

Usage
mx.symbol.nansum(...)

Arguments
data NDArray-or-Symbol The input
axis Shape or None, optional, default=None The axis or axes along which to perform the reduction.
   The default, `axis=()`, will compute over all elements into a scalar array with shape `(1,)`.
   If `axis` is int, a reduction is performed on a particular axis.
   If `axis` is a tuple of ints, a reduction is performed on all the axes specified in the tuple.
   If `exclude` is true, reduction will be performed on the axes that are NOT in axis instead.
   Negative values means indexing from right to left.
keepdims boolean, optional, default=0 If this is set to ‘True’, the reduced axes are left in the result as dimension with size one.
exclude boolean, optional, default=0 Whether to perform reduction on axis that are NOT in axis instead.
name string, optional Name of the resulting symbol.
Details
Defined in src/operator/tensor/broadcast_reduce_sum_value.cc:L102

Value
out The result mx.symbol

---

mx.symbol.negative negative: Numerical negative of the argument, element-wise.

Description
The storage type of “negative” output depends upon the input storage type:

Usage
mx.symbol.negative(....)

Arguments
data NDArray-or-Symbol The input array.
named string, optional Name of the resulting symbol.

Details
- negative(default) = default - negative(row_sparse) = row_sparse - negative(csr) = csr

Value
out The result mx.symbol

---

mx.symbol.norm norm: Computes the norm on an NDArray.

Description
This operator computes the norm on an NDArray with the specified axis, depending on the value of
the ord parameter. By default, it computes the L2 norm on the entire array. Currently only ord=2
supports sparse ndarrays.

Usage
mx.symbol.norm(....)
mx.symbol.normal

Arguments

data NDArray-or-Symbol The input

ord int, optional, default=’2’ Order of the norm. Currently ord=1 and ord=2 is supported.

axis Shape or None, optional, default=None The axis or axes along which to perform the reduction. The default, ‘axis=()’, will compute over all elements into a scalar array with shape ‘(1,)’. If ‘axis’ is int, a reduction is performed on a particular axis. If ‘axis’ is a 2-tuple, it specifies the axes that hold 2-D matrices, and the matrix norms of these matrices are computed.

keepdims boolean, optional, default=0 If this is set to ‘True’, the reduced axis is left in the result as dimension with size one.

name string, optional Name of the resulting symbol.

Details

Examples::

x = [[[1, 2], [3, 4]], [[2, 2], [5, 6]]

norm(x, ord=2, axis=1) = [[3.1622777 4.472136 ] [5.3851647 6.3245554]]

norm(x, ord=1, axis=1) = [[4., 6.], [7., 8.]]

rsp = x.cast_storage('row_sparse')

norm(rsp) = [5.47722578]

csr = x.cast_storage('csr')

norm(csr) = [5.47722578]

Defined in src/operator/tensor/broadcastReduceNormValue.cc:L89

Value

out The result mx.symbol

mx.symbol.normal

normal:Draw random samples from a normal (Gaussian) distribution.

Description

.. note:: The existing alias “normal” is deprecated.

Usage

mx.symbol.normal(...)
mx.symbol.ones_like

**Arguments**

- **loc**  
  float, optional, default=0 Mean of the distribution.

- **scale**  
  float, optional, default=1 Standard deviation of the distribution.

- **shape**  
  Shape(tuple), optional, default=None Shape of the output.

- **ctx**  
  string, optional, default="" Context of output, in format [cpu|gpu|cpu_pinned][n]. Only used for imperative calls.

- **dtype**  
  'None', 'float16', 'float32', 'float64',optional, default='None' DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).

- **name**  
  string, optional Name of the resulting symbol.

**Details**

Samples are distributed according to a normal distribution parametrized by *loc* (mean) and *scale* (standard deviation).

Example::

```python
normal(loc=0, scale=1, shape=(2,2)) = [[ 1.89171135, -1.16881478], [-1.23474145, 1.55807114]]
```

Defined in src/operator/random/sample_op.cc:L113

**Value**

- **out**  
  The result mx.symbol

---

mx.symbol.ones_like  

ones_like:Return an array of ones with the same shape and type as the input array.

**Description**

Examples::

**Usage**

mx.symbol.ones_like(...)

**Arguments**

- **data**  
  NDArray-or-Symbol The input

- **name**  
  string, optional Name of the resulting symbol.

**Details**

```python
x = [[ 0., 0., 0.], [ 0., 0., 0.]]
ones_like(x) = [[ 1., 1., 1.], [ 1., 1., 1.]]
```
mx.symbol.one_hot

Value

out The result mx.symbol

mx.symbol.one_hot

one_hot: Returns a one-hot array.

Description

The locations represented by ‘indices’ take value ‘on_value’, while all other locations take value ‘off_value’.

Usage

mx.symbol.one_hot(...)

Arguments

indices NDArray-or-Symbol array of locations where to set on_value
depth int, required Depth of the one hot dimension.
on_value double, optional, default=1 The value assigned to the locations represented by indices.
off_value double, optional, default=0 The value assigned to the locations not represented by indices.
dtype 'bfloat16', 'float16', 'float32', 'float64', 'int32', 'int64', 'int8', 'uint8', optional,
default='float32' DType of the output
name string, optional Name of the resulting symbol.

Details

‘one_hot’ operation with ‘indices’ of shape “(i0, i1)” and ‘depth’ of “d” would result in an output array of shape “(i0, i1, d)” with:
output[i,j,:] = off_value output[i,j,indices[i,j]] = on_value
Examples:
one_hot([1,0,2,0], 3) = [[ 0. 1. 0. ] [ 1. 0. 0. ] [ 0. 0. 1. ] [ 1. 0. 0. ]]
one_hot([1,0,2,0], 3, on_value=8, off_value=1, dtype='int32') = [[1 8 1] [8 1 1] [1 8] [8 1 1]]
one_hot([[1,0],[1,0],[2,0]], 3) = [[0. 1. 0.] [1. 0. 0.]]
[ [ 0. 0. 1.] [ 1. 0. 0. ]]
Defined in src/operator/tensor/indexing_op.cc:L883

Value

out The result mx.symbol
mx.symbol.Pad

Pad:

Pads an input array with a constant or edge values of the array.

Description

.. note:: 'Pad' is deprecated. Use 'pad' instead.

Usage

mx.symbol.Pad(…)

Arguments

data

NDArray-or-Symbol An n-dimensional input array.

mode

'constant', 'edge', 'reflect', required Padding type to use. "constant" pads with 'constant_value' "edge" pads using the edge values of the input array "reflect" pads by reflecting values with respect to the edges.

pad.width

Shape(tuple), required Widths of the padding regions applied to the edges of each axis. It is a tuple of integer padding widths for each axis of the format "(before_1, after_1, ... , before_N, after_N)". It should be of length "2*N" where "N" is the number of dimensions of the array. This is equivalent to pad_width in numpy.pad, but flattened.

custom.value

double, optional, default=0 The value used for padding when 'mode' is "constant".

name

string, optional Name of the resulting symbol.

Details

.. note:: Current implementation only supports 4D and 5D input arrays with padding applied only on axes 1, 2 and 3. Expects axes 4 and 5 in 'pad_width' to be zero.

This operation pads an input array with either a 'constant_value' or edge values along each axis of the input array. The amount of padding is specified by 'pad_width'.

'pad_width' is a tuple of integer padding widths for each axis of the format "(before_1, after_1, ... , before_N, after_N)". The 'pad_width' should be of length "2*N" where "N" is the number of dimensions of the array.

For dimension "N" of the input array, "before_N" and "after_N" indicates how many values to add before and after the elements of the array along dimension "N". The widths of the higher two dimensions "before_2", "after_2", "before_2", "after_2" must be 0.

Example::

x = [[[ 1. 2. 3. ] [ 4. 5. 6.]]
[[ 7. 8. 9. ] [ 10. 11. 12.]]
[[ 11. 12. 13. ] [ 14. 15. 16.]]
[[ 17. 18. 19. ] [ 20. 21. 22.]]]
mx.symbol.pad

pad(x, mode="edge", pad_width=(0, 0, 0, 1, 1, 1, 1, 1)) =
[[[1. 1. 2. 3. 3. ] [ 1. 1. 2. 3. 3. ] [ 4. 4. 5. 6. 6. ] [ 4. 4. 5. 6. 6. ]]
[[ 7. 7. 8. 9. 9. ] [ 7. 7. 8. 9. 9. ] [ 10. 10. 11. 12. 12. ] [ 10. 10. 11. 12. 12. ]]
[[ 17. 17. 18. 19. 19. ] [ 17. 17. 18. 19. 19. ] [ 20. 20. 21. 22. 22. ] [ 20. 20. 21. 22. 22. ]]]

pad(x, mode="constant", constant_value=0, pad_width=(0, 0, 0, 1, 1, 1, 1, 1)) =
[[[0. 0. 0. 0. 0. ] [ 0. 1. 2. 3. 0. ] [ 0. 4. 5. 6. 0. ] [ 0. 0. 0. 0. 0. ]]
[[ 0. 0. 0. 0. 0. ] [ 0. 7. 8. 9. 0. ] [ 0. 10. 11. 12. 0. ] [ 0. 0. 0. 0. 0. ]]
[[ 0. 0. 0. 0. 0. ] [ 0. 11. 12. 13. 0. ] [ 0. 14. 15. 16. 0. ] [ 0. 0. 0. 0. 0. ]]
[[ 0. 0. 0. 0. 0. ] [ 0. 17. 18. 19. 0. ] [ 0. 20. 21. 22. 0. ] [ 0. 0. 0. 0. 0. ]]]

Defined in src/operator/pad.cc:L766

Value

out The result mx.symbol

mx.symbol.pick

pick: Picks elements from an input array according to the input indices along the given axis.

Description

Given an input array of shape “(d0, d1)“ and indices of shape “(i0,)“, the result will be an output array of shape “(i0,)“ with::
Usage

mx.symbol.pick(...)

Arguments

data NDArray-or-Symbol The input array

index NDArray-or-Symbol The index array

axis int or None, optional, default='-1' int or None. The axis to picking the elements. Negative values means indexing from right to left. If is ‘None’, the elements in the index w.r.t the flattened input will be picked.

keepdims boolean, optional, default=0 If true, the axis where we pick the elements is left in the result as dimension with size one.

mode 'clip', 'wrap', optional, default='clip' Specify how out-of-bound indices behave. Default is "clip". "clip" means clip to the range. So, if all indices mentioned are too large, they are replaced by the index that addresses the last element along an axis. "wrap" means to wrap around.

name string, optional Name of the resulting symbol.

details

output[i] = input[i, indices[i]]

By default, if any index mentioned is too large, it is replaced by the index that addresses the last element along an axis (the ‘clip’ mode).

This function supports n-dimensional input and (n-1)-dimensional indices arrays.

Examples::

x = [[ 1., 2.], [ 3., 4.], [ 5., 6.]]
// picks elements with specified indices along axis 0 pick(x, y=[0,1], 0) = [ 1., 4.]
// picks elements with specified indices along axis 1 pick(x, y=[0,1,0], 1) = [ 1., 4., 5.]
// picks elements with specified indices along axis 1 using 'wrap' mode // to place indicies that would normally be out of bounds pick(x, y=[2,-1,-2], 1, mode='wrap') = [ 1., 4., 5.]

y = [[ 1.], [ 0.], [ 2.]]
// picks elements with specified indices along axis 1 and dims are maintained pick(x, y, 1, keep dims=True) = [[ 2.], [ 3.], [ 6.]]

Defined in src/operator/tensor/broadcast_reduce_op_index.cc:L151

Value

out The result mx.symbol
**Description**

The shapes for 1-D pooling are

**Usage**

`mx.symbol.Pooling(...)`

**Arguments**

- `data` NDArray-or-Symbol: Input data to the pooling operator.
- `kernel` Shape(tuple), optional, default=[]: Pooling kernel size: (y, x) or (d, y, x).
- `pool.type` 'avg', 'lp', 'max', 'sum', optional, default='max': Pooling type to be applied.
- `global.pool` boolean, optional, default=0: Ignore kernel size, do global pooling based on current input feature map.
- `cudnn.off` boolean, optional, default=0: Turn off cudnn pooling and use MXNet pooling operator.
- `pooling.convention` 'full', 'same', 'valid', optional, default='valid': Pooling convention to be applied.
- `stride` Shape(tuple), optional, default=[]: Stride: for pooling (y, x) or (d, y, x). Defaults to 1 for each dimension.
- `pad` Shape(tuple), optional, default=[]: Pad for pooling: (y, x) or (d, y, x). Defaults to no padding.
- `p.value` int or None, optional, default='None': Value of p for Lp pooling, can be 1 or 2, required for Lp Pooling.
- `count.include.pad` boolean or None, optional, default=None: Only used for AvgPool, specify whether to count padding elements for average calculation. For example, with a 5*5 kernel on a 3*3 corner of an image, the sum of the 9 valid elements will be divided by 25 if this is set to true, or it will be divided by 9 if this is set to false. Defaults to true.
- `layout` None, 'NCDHW', 'NCHW', 'NCW', 'NDHWC', 'NHWC', 'NWC', optional, default='None': Set layout for input and output. Empty for default layout: NCW for 1d, NCHW for 2d and NCDHW for 3d.
- `name` string, optional: Name of the resulting symbol.
Details

- **data** and **out**: *(batch_size, channel, width)* (NCW layout) or *(batch_size, width, channel)* (NWC layout),

The shapes for 2-D pooling are

- **data** and **out**: *(batch_size, channel, height, width)* (NCHW layout) or *(batch_size, height, width, channel)* (NHWC layout),

out_height = f(height, kernel[0], pad[0], stride[0])
out_width = f(width, kernel[1], pad[1], stride[1])

The definition of *f* depends on “pooling_convention”, which has two options:

- **valid** (default):=
  
f(x, k, p, s) = floor((x+2*p-k)/s)+1

- **full**, which is compatible with Caffe:=
  
f(x, k, p, s) = ceil((x+2*p-k)/s)+1

When “global_pool” is set to be true, then global pooling is performed. It will reset “kernel=(height, width)” and set the appropriate padding to 0.

Three pooling options are supported by “pool_type”:

- **avg**: average pooling - **max**: max pooling - **sum**: sum pooling - **lp**: Lp pooling

For 3-D pooling, an additional *depth* dimension is added before *height*. Namely the input data and output will have shape *(batch_size, channel, depth, height, width)* (NCDHW layout) or *(batch_size, depth, height, width, channel)* (NDHWC layout).

Notes on Lp pooling:

Lp pooling was first introduced by this paper: https://arxiv.org/pdf/1204.3968.pdf. L-1 pooling is simply sum pooling, while L-inf pooling is simply max pooling. We can see that Lp pooling stands between those two, in practice the most common value for p is 2.

For each window “X”, the mathematical expression for Lp pooling is:

:math:`f(X) = \sqrt[p]{\sum_x X^p}`

Defined in src/operator/nn/pooling.cc:L417

Value

out The result mx.symbol

mx.symbol.Pooling_v1

Pooling_v1: This operator is DEPRECATED. Perform pooling on the input.

Description

The shapes for 2-D pooling is

Usage

mx.symbol.Pooling_v1(...)
Arguments

data NDArray-or-Symbol Input data to the pooling operator.
kernel Shape(tuple), optional, default=[] pooling kernel size: (y, x) or (d, y, x)
pool.type 'avg', 'max', 'sum', optional, default='max' Pooling type to be applied.
global.pool boolean, optional, default=0 Ignore kernel size, do global pooling based on current input feature map.
pooling.convention 'full', 'valid', optional, default='valid' Pooling convention to be applied.
stride Shape(tuple), optional, default=[] stride: for pooling (y, x) or (d, y, x)
pad Shape(tuple), optional, default=[] pad for pooling: (y, x) or (d, y, x)
name string, optional Name of the resulting symbol.

Details

- **data**: *(batch_size, channel, height, width)* - **out**: *(batch_size, num_filter, out_height, out_width)*, with:

out_height = f(height, kernel[0], pad[0], stride[0])
out_width = f(width, kernel[1], pad[1], stride[1])

The definition of *f* depends on “pooling_convention”, which has two options:

- **valid** (default):

  f(x, k, p, s) = floor((x+2*p-k)/s)+1

- **full**, which is compatible with Caffe:

  f(x, k, p, s) = ceil((x+2*p-k)/s)+1

But “global_pool” is set to be true, then do a global pooling, namely reset “kernel=(height, width)“.

Three pooling options are supported by “pool_type“:

- **avg**: average pooling - **max**: max pooling - **sum**: sum pooling

1-D pooling is special case of 2-D pooling with *weight=1* and *kernel[1]=1*.

For 3-D pooling, an additional *depth* dimension is added before *height*. Namely the input data will have shape *(batch_size, channel, depth, height, width)*.

Defined in src/operator/pooling_v1.cc:L104

Value

out The result mx.symbol
mx.symbol.preloaded_multi_mp_sgd_mom_update

**Description**

Momentum update has better convergence rates on neural networks. Mathematically it looks like below:

**Usage**

mx.symbol.preloaded_multi_mp_sgd_mom_update(...)

**Arguments**

- **data**
  NDArray-or-Symbol[] Weights, gradients, momentums, learning rates and weight decays
- **momentum**
  float, optional, default=0 The decay rate of momentum estimates at each epoch.
- **rescale.grad**
  float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
- **clip.gradient**
  float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient]
  If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).
- **num.weights**
  int, optional, default='1' Number of updated weights.
- **name**
  string, optional Name of the resulting symbol.

**Details**

.. math::

   \begin{align*}
   v_1 & = \alpha \cdot \nabla J(W_0) \\
   v_t & = \gamma v_{t-1} - \alpha \cdot \nabla J(W_{t-1}) \\
   W_t & = W_{t-1} + v_t
   \end{align*}

It updates the weights using::

   v = momentum * v - learning_rate * gradient weight += v

Where the parameter “momentum” is the decay rate of momentum estimates at each epoch.

Defined in src/operator/contrib/preloaded_multi_sgd.cc:L200

**Value**

out The result mx.symbol
mx.symbol.preloaded_multi_mp_sgd_update

Description

It updates the weights using:

Usage

mx.symbol.preloaded_multi_mp_sgd_update(...)

Arguments

data NDArray-or-Symbol[] Weights, gradients, learning rates and weight decays
rescale.grad float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
clip.gradient float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient]
If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).
um.weights int, optional, default='1’ Number of updated weights.
name string, optional Name of the resulting symbol.

Details

weight = weight - learning_rate * (gradient + wd * weight)

Defined in src/operator/contrib/preloaded_multi_sgd.cc:L140

Value

out The result mx.symbol

mx.symbol.preloaded_multi_sgd_mom_update

preloaded_multi_sgd_mom_update: Momentum update function for Stochastic Gradient Descent (SGD) optimizer.

Description

Momentum update has better convergence rates on neural networks. Mathematically it looks like below:

Usage

mx.symbol.preloaded_multi_sgd_mom_update(...)
**Arguments**

- **data**: NDArray-or-Symbol[] Weights, gradients, momentum, learning rates and weight decays
- **momentum**: float, optional, default=0 The decay rate of momentum estimates at each epoch.
- **rescale.grad**: float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
- **clip.gradient**: float, optional, default=-1 Clip gradient to the range of [-clip.gradient, clip.gradient] If clip.gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip.gradient), -clip.gradient).
- **num.weights**: int, optional, default='1' Number of updated weights.
- **name**: string, optional Name of the resulting symbol.

**Details**

It updates the weights using::

\[ v_1 = \alpha \nabla J(W_0) \vspace{1mm} \]

\[ v_t = \gamma v_{t-1} - \alpha \nabla J(W_{t-1}) \vspace{1mm} \]

\[ W_t = W_{t-1} + v_t \vspace{1mm} \]

where the parameter “momentum“ is the decay rate of momentum estimates at each epoch.

Defined in src/operator/contrib/preloaded_multi_sgd.cc:L91

out The result mx.symbol

---

mx.symbol.prod

prod: Computes the product of array elements over given axes.

Description

Defined in src/operator/tensor/./broadcast_reduce_op.h:L31

Usage

mx.symbol.prod(...)

Arguments

data NDArray-or-Symbol The input
axis Shape or None, optional, default=None The axis or axes along which to perform the reduction.
   The default, 'axis=()', will compute over all elements into a scalar array with shape '(1,)'.
   If 'axis' is int, a reduction is performed on a particular axis.
   If 'axis' is a tuple of ints, a reduction is performed on all the axes specified in the tuple.
   If 'exclude' is true, reduction will be performed on the axes that are NOT in axis instead.
   Negative values means indexing from right to left.
keepdims boolean, optional, default=0 If this is set to 'True', the reduced axes are left in the result as dimension with size one.
exclude boolean, optional, default=0 Whether to perform reduction on axis that are NOT in axis instead.
name string, optional Name of the resulting symbol.

Value

out The result mx.symbol
mx.symbol.radians

radians: Converts each element of the input array from degrees to radians.

Description

.. math:: \text{radians}([0, 90, 180, 270, 360]) = [0, \pi/2, \pi, 3\pi/2, 2\pi]

Usage

mx.symbol.radians(...)

Arguments

data NDArray-or-Symbol The input array.
name string, optional Name of the resulting symbol.

Details

The storage type of “radians“ output depends upon the input storage type:
- radians(default) = default - radians(row_sparse) = row_sparse - radians(csr) = csr
Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L351

Value

out The result mx.symbol

mx.symbol.random_exponential

random_exponential: Draw random samples from an exponential distribution.

Description

Samples are distributed according to an exponential distribution parametrized by *lambda* (rate).

Usage

mx.symbol.random_exponential(...)
Arguments

- **lam**: float, optional, default=1 Lambda parameter (rate) of the exponential distribution.
- **shape**: Shape(tuple), optional, default=None Shape of the output.
- **ctx**: string, optional, default=“Context of output, in format [cpu|gpu|cpu_pinned](n). Only used for imperative calls.
- **dtype**: ’None’, ’float16’, ’float32’, ’float64’, optional, default=’None’ DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).
- **name**: string, optional Name of the resulting symbol.

Details

Example::

    exponential(lam=4, shape=(2,2)) = [[ 0.0097189 , 0.08999364], [ 0.04146638, 0.31715935]]

Defined in src/operator/random/sample_op.cc:L137

Value

- **out**: The result mx.symbol

mx.symbol.random_gamma

random_gamma:Draw random samples from a gamma distribution.

Description

Samples are distributed according to a gamma distribution parametrized by *alpha* (shape) and *beta* (scale).

Usage

mx.symbol.random_gamma(...)

Arguments

- **alpha**: float, optional, default=1 Alpha parameter (shape) of the gamma distribution.
- **beta**: float, optional, default=1 Beta parameter (scale) of the gamma distribution.
- **shape**: Shape(tuple), optional, default=None Shape of the output.
- **ctx**: string, optional, default=“Context of output, in format [cpu|gpu|cpu_pinned](n). Only used for imperative calls.
- **dtype**: ’None’, ’float16’, ’float32’, ’float64’, optional, default=’None’ DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).
- **name**: string, optional Name of the resulting symbol.
random_generalized_negative_binomial

mx.symbol.random_generalized_negative_binomial

random_generalized_negative_binomial: Draw random samples from a generalized negative binomial distribution.

Description

Samples are distributed according to a generalized negative binomial distribution parametrized by *mu* (mean) and *alpha* (dispersion). *alpha* is defined as *1/k* where *k* is the failure limit of the number of unsuccessful experiments (generalized to real numbers). Samples will always be returned as a floating point data type.

Usage

```
mx.symbol.random_generalized_negative_binomial(...)
```

Arguments

- **mu**: float, optional, default=1 Mean of the negative binomial distribution.
- **alpha**: float, optional, default=1 Alpha (dispersion) parameter of the negative binomial distribution.
- **shape**: Shape(tuple), optional, default=None Shape of the output.
- **ctx**: string, optional, default="" Context of output, in format [cpu|gpu|cpu_pinned](n).
  Only used for imperative calls.
- **dtype**: 'None', 'float16', 'float32', 'float64', optional, default='None' DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).
- **name**: string, optional Name of the resulting symbol.

Details

Example::

```
generalized_negative_binomial(mu=2.0, alpha=0.3, shape=(2,2)) = [[ 2., 1.], [ 6., 4.]]
```

Defined in src/operator/random/sample_op.cc:L179

Value

`out` The result mx.symbol
**random_negative_binomial**

*random_negative_binomial*:

*Draw random samples from a negative binomial distribution.*

**Description**

Samples are distributed according to a negative binomial distribution parametrized by \( k \) (limit of unsuccessful experiments) and \( p \) (failure probability in each experiment). Samples will always be returned as a floating point data type.

**Usage**

mx.symbol.random_negative_binomial(...)

**Arguments**

- **k**: int, optional, default='1' Limit of unsuccessful experiments.
- **p**: float, optional, default=1 Failure probability in each experiment.
- **shape**: Shape(tuple), optional, default=None Shape of the output.
- **ctx**: string, optional, default='' Context of output, in format [cpu|gpu|cpu_pinned](n). Only used for imperative calls.
- **dtype**: 'None', 'float16', 'float32', 'float64', optional, default='None' DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).
- **name**: string, optional Name of the resulting symbol.

**Details**

Example::

    negative_binomial(k=3, p=0.4, shape=(2,2)) = [[ 4., 7.], [ 2., 5.]]

Defined in src/operator/random/sample_op.cc:L164

**Value**

- **out**: The result mx.symbol
random_normal: Draw random samples from a normal (Gaussian) distribution.

**Description**

.. note:: The existing alias “normal” is deprecated.

**Usage**

```python
mx.symbol.random_normal(...)
```

**Arguments**

- `loc` float, optional, default=0 Mean of the distribution.
- `scale` float, optional, default=1 Standard deviation of the distribution.
- `shape` Shape(tuple), optional, default=None Shape of the output.
- `ctx` string, optional, default=“ Context of output, in format [cpu|gpu|cpu_pinned](n). Only used for imperative calls.
- `dtype` 'None', 'float16', 'float32', 'float64', optional, default='None' DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).
- `name` string, optional Name of the resulting symbol.

**Details**

Samples are distributed according to a normal distribution parametrized by *loc* (mean) and *scale* (standard deviation).

Example::

```python
normal(loc=0, scale=1, shape=(2,2)) = [[1.89171135, -1.16881478], [-1.23474145, 1.55807114]]
```

Defined in src/operator/random/sample_op.cc:L113

**Value**

out The result mx.symbol
mx.symbol.random_pdf_dirichlet

random_pdf_dirichlet: Computes the value of the PDF of *sample* of Dirichlet distributions with parameter *alpha*.

Description

The shape of *alpha* must match the leftmost subshape of *sample*. That is, *sample* can have the same shape as *alpha*, in which case the output contains one density per distribution, or *sample* can be a tensor of tensors with that shape, in which case the output is a tensor of densities such that the densities at index *i* in the output are given by the samples at index *i* in *sample* parameterized by the value of *alpha* at index *i*.

Usage

mx.symbol.random_pdf_dirichlet(...)

Arguments

- sample: NDArray-or-Symbol Samples from the distributions.
- alpha: NDArray-or-Symbol Concentration parameters of the distributions.
- is.log: boolean, optional, default=0 If set, compute the density of the log-probability instead of the probability.
- name: string, optional Name of the resulting symbol.

Details

Examples:

\[
\text{random_pdf_dirichlet(sample=[[1,2],[2,3],[3,4]], alpha=[2.5, 2.5]) = [38.413498, 199.60245, 564.56085]}
\]
\[
\text{sample = [[[1, 2, 3], [10, 20, 30], [100, 200, 300]], [[0.1, 0.2, 0.3], [0.01, 0.02, 0.03], [0.001, 0.002, 0.003]]]}
\]
\[
\text{random_pdf_dirichlet(sample=sample, alpha=[0.1, 0.4, 0.9]) = [[2.3257459e-02, 5.8420084e-04, 1.4674458e-05], [9.2589635e-01, 3.6860607e+01, 1.4674468e+03]]}
\]

Value

- out: The result mx.symbol
random_pdf_generalized_negative_binomial: Computes the value of the PDF of *sample* of generalized negative binomial distributions with parameters *mu* (mean) and *alpha* (dispersion). This can be understood as a reparameterization of the negative binomial, where *k* = 1 / alpha and *p* = 1 / (mu \alpha + 1).

Description

*mu* and *alpha* must have the same shape, which must match the leftmost subshape of *sample*. That is, *sample* can have the same shape as *mu* and *alpha*, in which case the output contains one density per distribution, or *sample* can be a tensor of tensors with that shape, in which case the output is a tensor of densities such that the densities at index *i* in the output are given by the samples at index *i* in *sample* parameterized by the values of *mu* and *alpha* at index *i*.

Usage

mx.symbol.random_pdf_generalized_negative_binomial(…)

Arguments

- sample: NDArray-or-Symbol Samples from the distributions.
- mu: NDArray-or-Symbol Means of the distributions.
- is.log: boolean, optional, default=0 If set, compute the density of the log-probability instead of the probability.
- alpha: NDArray-or-Symbol Alpha (dispersion) parameters of the distributions.
- name: string, optional Name of the resulting symbol.

Details

Examples:

```python
code
random_pdf_generalized_negative_binomial(sample=[[1, 2, 3, 4]], alpha=[1], mu=[1]) = [[0.25, 0.125, 0.0625, 0.03125]]
sample = [[1,2,3,4], [1,2,3,4]] random_pdf_generalized_negative_binomial(sample=sample, alpha=[1, 0.6666], mu=[1, 1.5]) = [[0.25, 0.125, 0.0625, 0.03125 ], [0.26517063, 0.16573331, 0.09667706, 0.05437994]]
```

Defined in src/operator/random/pdf_op.cc:L314

Value

out The result mx.symbol
mx.symbol.random_pdf_negative_binomial

random_pdf_negative_binomial: Computes the value of the PDF of samples of negative binomial distributions with parameters *k* (failure limit) and *p* (failure probability).

**Description**

*k* and *p* must have the same shape, which must match the leftmost subshape of *sample*. That is, *sample* can have the same shape as *k* and *p*, in which case the output contains one density per distribution, or *sample* can be a tensor of tensors with that shape, in which case the output is a tensor of densities such that the densities at index *i* in *sample* are given by the samples at index *i* in *sample* parameterized by the values of *k* and *p* at index *i*.

**Usage**

mx.symbol.random_pdf_negative_binomial(...)

**Arguments**

- **sample**: NDArray-or-Symbol Samples from the distributions.
- **k**: NDArray-or-Symbol Limits of unsuccessful experiments.
- **is.log**: boolean, optional, default=0 If set, compute the density of the log-probability instead of the probability.
- **p**: NDArray-or-Symbol Failure probabilities in each experiment.
- **name**: string, optional Name of the resulting symbol.

**Details**

Examples::

    random_pdf_negative_binomial(sample=[[1,2,3,4]], k=[1], p=a[0.5]) = [[0.25, 0.125, 0.0625, 0.03125]]
    # Note that k may be real-valued sample = [[1,2,3,4], [1,2,3,4]] random_pdf_negative_binomial(sample=sample, k=[1, 1.5], p=[0.5, 0.5]) = [[0.25, 0.125, 0.0625, 0.03125 ], [0.26516506, 0.16572815, 0.09667476, 0.05437956]]

Defined in src/operator/random/pdf_op.cc:L310

**Value**

- **out**: The result mx.symbol
mx.symbol.random_pdf_normal

random_pdf_normal: Computes the value of the PDF of *sample* of normal distributions with parameters *mu* (mean) and *sigma* (standard deviation).

Description

*mu* and *sigma* must have the same shape, which must match the leftmost subshape of *sample*. That is, *sample* can have the same shape as *mu* and *sigma*, in which case the output contains one density per distribution, or *sample* can be a tensor of tensors with that shape, in which case the output is a tensor of densities such that the densities at index *i* in the output are given by the samples at index *i* in *sample* parameterized by the values of *mu* and *sigma* at index *i*.

Usage

mx.symbol.random_pdf_normal(...)

Arguments

sample: NDArray-or-Symbol Samples from the distributions.
mu: NDArray-or-Symbol Means of the distributions.
is.log: boolean, optional, default=0 If set, compute the density of the log-probability instead of the probability.
sigma: NDArray-or-Symbol Standard deviations of the distributions.
name: string, optional Name of the resulting symbol.

Details

Examples::
sample = [[-2, -1, 0, 1, 2]]
random_pdf_normal(sample=sample, mu=[0], sigma=[1]) = [[0.05399097, 0.24197073, 0.3989423, 0.24197073, 0.05399097]]
random_pdf_normal(sample=sample*2, mu=[0,0], sigma=[1,2]) = [[0.05399097, 0.24197073, 0.3989423, 0.24197073, 0.05399097], [0.12098537, 0.17603266, 0.19947115, 0.17603266, 0.12098537]]

Defined in src/operator/random/pdf_op.cc:L300

Value

out The result mx.symbol
mx.symbol.random_pdf_poisson

random_pdf_poisson: Computes the value of the PDF of *sample* of Poisson distributions with parameters *lam* (rate).

**Description**

The shape of *lam* must match the leftmost subshape of *sample*. That is, *sample* can have the same shape as *lam*, in which case the output contains one density per distribution, or *sample* can be a tensor of tensors with that shape, in which case the output is a tensor of densities such that the densities at index *i* in the output are given by the samples at index *i* in *sample* parameterized by the value of *lam* at index *i*.

**Usage**

mx.symbol.random_pdf_poisson(...)

**Arguments**

- **sample**: NDArray-or-Symbol. Samples from the distributions.
- **lam**: NDArray-or-Symbol. Lambda (rate) parameters of the distributions.
- **is.log**: boolean, optional, default=0. If set, compute the density of the log-probability instead of the probability.
- **name**: string, optional. Name of the resulting symbol.

**Details**

Examples:

```
random_pdf_poisson(sample=[[0,1,2,3]], lam=[1]) = [[0.36787945, 0.36787945, 0.18393973, 0.06131324]]
sample = [[0,1,2,3], [0,1,2,3], [0,1,2,3]]
random_pdf_poisson(sample=sample, lam=[1,2,3]) =
[[0.36787945, 0.36787945, 0.18393973, 0.06131324],
[0.13533528, 0.27067056, 0.27067056, 0.18044704],
[0.04978707, 0.14936121, 0.22404182, 0.22404182]]
```

Defined in src/operator/random/pdf_op.cc:L307

**Value**

out The result mx.symbol
**mx.symbol.random_pdf_uniform**

Computes the value of the PDF of *sample* of uniform distributions on the intervals given by *[low,high]*.

**Description**

*low* and *high* must have the same shape, which must match the leftmost subshape of *sample*.
That is, *sample* can have the same shape as *low* and *high*, in which case the output contains one density per distribution, or *sample* can be a tensor of tensors with that shape, in which case the output is a tensor of densities such that the densities at index *i* in the output are given by the samples at index *i* in *sample* parameterized by the values of *low* and *high* at index *i*.

**Usage**

mx.symbol.random_pdf_uniform(...)

**Arguments**

- **sample**: NDArray-or-Symbol. Samples from the distributions.
- **low**: NDArray-or-Symbol. Lower bounds of the distributions.
- **is.log**: boolean, optional, default=0. If set, compute the density of the log-probability instead of the probability.
- **high**: NDArray-or-Symbol. Upper bounds of the distributions.
- **name**: string, optional. Name of the resulting symbol.

**Details**

Examples::

random_pdf_uniform(sample=[[1,2,3,4]], low=[0], high=[10]) = [0.1, 0.1, 0.1, 0.1]

sample = [[[1, 2, 3], [1, 2, 3]], [[1, 2, 3], [1, 2, 3]]] low = [[0, 0], [0, 0]] high = [[5, 10], [15, 20]] random_pdf_uniform(sample=sample, low=low, high=high) = [[0.06667, 0.06667, 0.06667], [0.05, 0.05, 0.05]]

Defined in src/operator/random/pdf_op.cc:L298

**Value**

out The result mx.symbol
mx.symbol.random_poisson

random_poisson: Draw random samples from a Poisson distribution.

Description

Samples are distributed according to a Poisson distribution parametrized by \( \lambda \) (rate). Samples will always be returned as a floating point data type.

Usage

mx.symbol.random_poisson(...)

Arguments

- lam: float, optional, default=1 Lambda parameter (rate) of the Poisson distribution.
- shape: Shape(tuple), optional, default=None Shape of the output.
- ctx: string, optional, default=" Context of output, in format [cpu|gpu|cpu_pinned][n]. Only used for imperative calls.
- dtype: 'None', 'float16', 'float32', 'float64', optional, default='None' DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).
- name: string, optional Name of the resulting symbol.

Details

Example::

    poisson(lam=4, shape=(2,2)) = [[ 5., 2.], [ 4., 6.]]

Defined in src/operator/random/sample_op.cc:L150

Value

- out: The result mx.symbol

mx.symbol.random_randint

random_randint: Draw random samples from a discrete uniform distribution.

Description

Samples are uniformly distributed over the half-open interval \([\text{low}, \text{high})\) (includes \(\text{low}\), but excludes \(\text{high}\)).
random_uniform: Draw random samples from a uniform distribution.

Description

.. note:: The existing alias “uniform” is deprecated.

Usage

mx.symbol.random_uniform(...)

Arguments

- **low** float, optional, default=0 Lower bound of the distribution.
- **high** float, optional, default=1 Upper bound of the distribution.
- **shape** Shape(tuple), optional, default=None Shape of the output.
- **ctx** string, optional, default=" Context of output, in format [cpu|gpu|cpu_pinned](n). Only used for imperative calls.
- **dtype** 'None', 'float16', 'float32', 'float64', optional, default='None' DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).
- **name** string, optional Name of the resulting symbol.
Details

Samples are uniformly distributed over the half-open interval *[low, high)* (includes *low*, but excludes *high*).

Example:

```
uniform(low=0, high=1, shape=(2,2)) = [[ 0.60276335, 0.85794562], [ 0.54488319, 0.84725171]]
```

Defined in src/operator/random/sample_op.cc:L96

Value

out The result mx.symbol
mx.symbol.rcbrt

rcbrt: Returns element-wise inverse cube-root value of the input.

Description

.. math:: rcbrt(x) = 1/\sqrt[3]{x}

Usage

mx.symbol.rcbrt(...)

Arguments

data NDArray-or-Symbol The input array.
name string, optional Name of the resulting symbol.

Details

Example::
rcbrt([1,8,-125]) = [1.0, 0.5, -0.2]

Defined in src/operator/tensor/elemwise_unary_op_pow.cc:L323

Value

out The result mx.symbol

mx.symbol.reciprocal

reciprocal: Returns the reciprocal of the argument, element-wise.

Description

Calculates 1/x.

Usage

mx.symbol.reciprocal(...)

Arguments

data NDArray-or-Symbol The input array.
name string, optional Name of the resulting symbol.
**mx.symbol.relu**

**Details**

Example:

```plaintext
tf.reciprocal([-2, 1, 3, 1.6, 0.2]) = [-0.5, 1.0, 0.33333334, 0.625, 5.0]
```

Defined in src/operator/tensor/elemwise_unary_op_pow.cc:L43

**Value**

`out` The result `mx.symbol`

---

```plaintext
mx.symbol.relu
relu: Computes rectified linear activation.
```

**Description**

.. math:: \text{max(features, 0)}

**Usage**

```python
mx.symbol.relu(...)
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>data</code></td>
<td>NDArray-or-Symbol</td>
<td>The input array.</td>
</tr>
<tr>
<td><code>name</code></td>
<td>string, optional</td>
<td>Name of the resulting symbol.</td>
</tr>
</tbody>
</table>

**Details**

The storage type of “relu” output depends upon the input storage type:

- `relu(default) = default`
- `relu(row_sparse) = row_sparse`
- `relu(csr) = csr`

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L85

**Value**

`out` The result `mx.symbol`
mx.symbol.repeat

repeat: Repeats elements of an array. By default, "repeat" flattens the input array into 1-D and then repeats the elements:

\[ x = \begin{bmatrix} 1, 2 \end{bmatrix}, \begin{bmatrix} 3, 4 \end{bmatrix} \]  
\[ \text{repeat}(x, \text{repeats}=2) = \begin{bmatrix} 1., 1., 2., 2., 3., 3., 4., 4. \end{bmatrix} \]

The parameter "axis" specifies the axis along which to perform repeat:

\[ \text{repeat}(x, \text{repeats}=2, \text{axis}=1) = \begin{bmatrix} 1., 1., 2., 2. \end{bmatrix}, \begin{bmatrix} 3., 3., 4., 4. \end{bmatrix} \]
\[ \text{repeat}(x, \text{repeats}=2, \text{axis}=0) = \begin{bmatrix} 1., 2. \end{bmatrix}, \begin{bmatrix} 1., 2. \end{bmatrix}, \begin{bmatrix} 3., 4. \end{bmatrix}, \begin{bmatrix} 3., 4. \end{bmatrix} \]
\[ \text{repeat}(x, \text{repeats}=2, \text{axis}=-1) = \begin{bmatrix} 1., 1., 2., 2. \end{bmatrix}, \begin{bmatrix} 3., 3., 4., 4. \end{bmatrix} \]

Description

Defined in src/operator/tensor/matrix_op.cc:L744

Usage

mx.symbol.repeat(...)

Arguments

- **data**: NDArray-or-Symbol Input data array
- **repeats**: int, required The number of repetitions for each element.
- **axis**: int or None, optional, default='None' The axis along which to repeat values. The negative numbers are interpreted counting from the backward. By default, use the flattened input array, and return a flat output array.
- **name**: string, optional Name of the resulting symbol.

Value

out The result mx.symbol

mx.symbol.reset_arrays

reset_arrays: Set to zero multiple arrays

Description

Defined in src/operator/contrib/reset_arrays.cc:L36

Usage

mx.symbol.reset_arrays(...)
mx.symbol.Reshape

Arguments

data NDArray-or-Symbol[] Arrays
num.arrays int, required number of input arrays.
name string, optional Name of the resulting symbol.

Value

out The result mx.symbol

mx.symbol.Reshape Reshape:Reshapes the input array. .. note:: “Reshape“ is deprecated, use “reshape“ Given an array and a shape, this function returns a copy of the array in the new shape. The shape is a tuple of integers such as (2,3,4). The size of the new shape should be same as the size of the input array. Example:: reshape([1,2,3,4], shape=(2,2)) = [[1,2], [3,4]] Some dimensions of the shape can take special values from the set 0, -1, -2, -3, -4. The significance of each is explained below: - “0“ copy this dimension from the input to the output shape. Example:: - input shape = (2,3,4), shape = (4,0,2), output shape = (4,3,2) - input shape = (2,3,4), shape = (2,0,0), output shape = (2,3,4) - “-1“ infers the dimension of the output shape by using the remainder of the input dimensions keeping the size of the new array same as that of the input array. At most one dimension of shape can be -1. Example:: - input shape = (2,3,4), shape = (6,1,-1), output shape = (6,1,4) - input shape = (2,3,4), shape = (3,-1,8), output shape = (3,1,8) - input shape = (2,3,4), shape = (-1,), output shape = (24,) - “-2“ copy all/remainder of the input dimensions to the output shape. Example:: - input shape = (2,3,4), shape = (-2,), output shape = (2,3,4) - input shape = (2,3,4), shape = (2,-2), output shape = (2,3,4) - input shape = (2,3,4), shape = (-2,1,1), output shape = (2,3,4,1,1) - “-3“ use the product of two consecutive dimensions of the input shape as the output dimension. Example:: - input shape = (2,3,4), shape = (-3,4), output shape = (6,4) - input shape = (2,3,4,5), shape = (-3,-3), output shape = (6,20) - input shape = (2,3,4), shape = (0,-3), output shape = (2,12) - input shape = (2,3,4), shape = (-3,-2), output shape = (6,4) - “-4“ split one dimension of the input into two dimensions passed subsequent to -4 in shape (can contain -1). Example:: - input shape = (2,3,4), shape = (-4,1,2,-2), output shape = (1,2,3,4) - input shape = (2,3,4), shape = (2,4,-1,3,-2), output shape = (2,1,3,4) If the argument ‘reverse‘ is set to 1, then the special values are inferred from right to left. Example:: - without reverse=1, for input shape = (10,5,4), shape = (-1,0), output shape would be (40,5) - with reverse=1, output shape will be (50,4).

Description

Defined in src/operator/tensor/matrix_op.cc:L175
Usage

    mx.symbol.Reshape(...)

Arguments

    data           NDArray-or-Symbol Input data to reshape.

    shape          Shape(tuple), optional, default=[] The target shape

    reverse        boolean, optional, default=0 If true then the special values are inferred from right to left

    target.shape  Shape(tuple), optional, default=[] (Deprecated! Use “shape” instead.) Target new shape. One and only one dim can be 0, in which case it will be inferred from the rest of dims

    keep.highest   boolean, optional, default=0 (Deprecated! Use “shape” instead.) Whether keep the highest dim unchanged. If set to true, then the first dim in target_shape is ignored, and always fixed as input

    name           string, optional Name of the resulting symbol.

Value

    out The result mx.symbol
mx.symbol.reshape

Reshapes the input array. .. note:: “Reshape” is deprecated, use “reshape” Given an array and a shape, this function returns a copy of the array in the new shape. The shape is a tuple of integers such as (2,3,4). The size of the new shape should be same as the size of the input array. Example:: reshape([1,2,3,4], shape=(2,2)) = [[1,2], [3,4]] Some dimensions of the shape can take special values from the set 0, -1, -2, -3, -4. The significance of each is explained below: - “0” copy this dimension from the input to the output shape. Example:: - input shape = (2,3,4), shape = (4,0,2), output shape = (4,3,2) - input shape = (2,3,4), shape = (2,0,0), output shape = (2,3,4) - “-1” infers the dimension of the output shape by using the remainder of the input dimensions keeping the size of the new array same as that of the input array. At most one dimension of shape can be -1. Example:: - input shape = (2,3,4), shape = (6,1,-1), output shape = (6,1,4) - input shape = (2,3,4), shape = (3,-1,8), output shape = (3,1,8) - input shape = (2,3,4), shape=(-1,1), output shape = (24,) - “-2” copy all/remainder of the input dimensions to the output shape. Example:: - input shape = (2,3,4), shape = (-2), output shape = (2,3,4) - input shape = (2,3,4), shape = (2,-2), output shape = (2,3,4) - input shape = (2,3,4), shape = (-2,1,1), output shape = (2,3,4,1) - “-3” use the product of two consecutive dimensions of the input shape as the output dimension. Example:: - input shape = (2,3,4), shape = (-3,4), output shape = (6,4) - input shape = (2,3,4), shape = (-3,-2), output shape = (6,4) - “-4” split one dimension of the input into two dimensions passed subsequent to -4 in shape (can contain -1). Example:: - input shape = (2,3,4), shape = (-4,1,2,-2), output shape = (1,2,3,4) - input shape = (2,3,4), shape = (2,-4,-1,3,-2), output shape = (2,1,3,4) If the argument ‘reverse’ is set to 1, then the special values are inferred from right to left. Example:: - without reverse=1, for input shape = (10,5,4), shape = (-1,0), output shape would be (40,5) - with reverse=1, output shape will be (50,4).

Description

Defined in src/operator/tensor/matrix_op.cc:L175

Usage

```
mx.symbol.reshape(...)
```

Arguments

data          NDArray-or-Symbol Input data to reshape.
shape         Shape(tuple), optional, default=[] The target shape
reverse        boolean, optional, default=0 If true then the special values are inferred from right to left
mx.symbol.reshape_like

target.shape
Shape(tuple), optional, default=[] (Deprecated! Use “shape” instead.) Target new shape. One and only one dim can be 0, in which case it will be inferred from the rest of dims

keep.highest
boolean, optional, default=0 (Deprecated! Use “shape” instead.) Whether keep the highest dim unchanged. If set to true, then the first dim in target_shape is ignored, and always fixed as input

name
string, optional Name of the resulting symbol.

Value
out The result mx.symbol

mx.symbol.reshape_like

reshape_like: Reshape some or all dimensions of ‘lhs’ to have the same shape as some or all dimensions of ‘rhs’.

Description
Returns a **view** of the ‘lhs’ array with a new shape without altering any data.

Usage
mx.symbol.reshape_like(...)

Arguments

1hs
NDArray-or-Symbol First input.

rhs
NDArray-or-Symbol Second input.

lhs.begin
int or None, optional, default=’None’ Defaults to 0. The beginning index along which the lhs dimensions are to be reshaped. Supports negative indices.

lhs.end
int or None, optional, default=’None’ Defaults to None. The ending index along which the lhs dimensions are to be used for reshaping. Supports negative indices.

rhs.begin
int or None, optional, default=’None’ Defaults to 0. The beginning index along which the rhs dimensions are to be used for reshaping. Supports negative indices.

rhs.end
int or None, optional, default=’None’ Defaults to None. The ending index along which the rhs dimensions are to be used for reshaping. Supports negative indices.

name
string, optional Name of the resulting symbol.
Details

Example::

x = [1, 2, 3, 4, 5, 6] y = [[0, -4], [3, 2], [2, 2]]
reshape_like(x, y) = [[1, 2], [3, 4], [5, 6]]

More precise control over how dimensions are inherited is achieved by specifying \ slices over the ‘lhs’ and ‘rhs’ array dimensions. Only the sliced ‘lhs’ dimensions \ are reshaped to the ‘rhs’ sliced dimensions, with the non-sliced ‘lhs’ dimensions staying the same.

Examples::

- lhs shape = (30, 7), rhs shape = (15, 2, 4), lhs_begin=0, rhs_begin=0, rhs_end=2, output shape = (15, 2, 7)
- lhs shape = (3, 5), rhs shape = (1, 15, 4), lhs_begin=0, rhs_begin=1, rhs_end=2, output shape = (15)

Negative indices are supported, and ‘None’ can be used for either ‘lhs_end’ or ‘rhs_end’ to indicate the end of the range.

Example::

- lhs shape = (30, 12), rhs shape = (4, 2, 2, 3), lhs_begin=-1, rhs_begin=1, rhs_end=None, output shape = (30, 2, 2, 3)

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L511

Value

out The result mx.symbol

mx.symbol.reverse

reverse: Reverses the order of elements along given axis while preserving array shape. Note: reverse and flip are equivalent. We use reverse in the following examples. Examples::

x = [[0, 1, 2, 3, 4], [5, 6, 7, 8, 9]]
reverse(x, axis=0) = [[5, 6, 7, 8, 9], [0, 1, 2, 3, 4]]
reverse(x, axis=1) = [[4, 3, 2, 1, 0], [9, 8, 7, 6, 5]]

Defined in src/operator/tensor/matrix_op.cc:L832

Usage

mx.symbol.reverse(...)
mx.symbol.rint

**Description**

.. note:: - For input “n.5” “rint” returns “n” while “round” returns “n+1”. - For input “-n.5” both “rint” and “round” returns “-n-1”.

**Usage**

mx.symbol.rint(...)

**Arguments**

data : NDArray-or-Symbol The input array.
name : string, optional Name of the resulting symbol.

**Details**

Example::

rint([-1.5, 1.5, -1.9, 1.9, 2.1]) = [-2., 1., -2., 2., 2.]

The storage type of “rint” output depends upon the input storage type:
- rint(default) = default - rint(row_sparse) = row_sparse - rint(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L798

**Value**

out The result mx.symbol

mx.symbol.rmspropalex_update

**Description**

‘RMSPropAlex’ is non-centered version of ‘RMSProp’.

**Usage**

mx.symbol.rmspropalex_update(...)
Arguments

Details

Define \(E[g^2]_t\) is the decaying average over past squared gradient and \(E[g]_t\) is the decaying average over past gradient.

\[
\begin{align*}
E[g^2]_t &= \gamma_1 \cdot E[g^2]_{t-1} + (1 - \gamma_1) \cdot g_t^2 \\
E[g]_t &= \gamma_1 \cdot E[g]_{t-1} + (1 - \gamma_1) \cdot g_t \\
\Delta_t &= \gamma_2 \cdot \Delta_{t-1} - \frac{\eta}{\sqrt{E[g^2]_t - E[g]_t^2}} g_t + \epsilon g_t
\end{align*}
\]

The update step is

\[
\theta_{t+1} = \theta_t + \Delta_t
\]

The RMSPropAlex code follows the version in http://arxiv.org/pdf/1308.0850v5.pdf Eq(38) - Eq(45) by Alex Graves, 2013.

Graves suggests the momentum term \(\gamma_1\) to be 0.95, \(\gamma_2\) to be 0.9 and the learning rate \(\eta\) to be 0.0001.

Defined in src/operator/optimizer_op.cc:L836

Value

out The result mx.symbol
Description

‘RMSprop’ is a variant of stochastic gradient descent where the gradients are divided by a cache which grows with the sum of squares of recent gradients.

Usage

mx.symbol.rmsprop_update(...)

Arguments

- weight: NDArray-or-Symbol Weight
- grad: NDArray-or-Symbol Gradient
- n: NDArray-or-Symbol n
- lr: float, required Learning rate
- gamma: float, optional, default=0.949999988 The decay rate of momentum estimates.
- epsilon: float, optional, default=9.99999994e-09 A small constant for numerical stability.
- wd: float, optional, default=0 Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
- rescale.grad: float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
- clip.gradient: float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient]
- clip.weights: float, optional, default=-1 Clip weights to the range of [-clip_weights, clip_weights]
- name: string, optional Name of the resulting symbol.

Details

‘RMSProp’ is similar to ‘AdaGrad’, a popular variant of ‘SGD’ which adaptively tunes the learning rate of each parameter. ‘AdaGrad’ lowers the learning rate for each parameter monotonically over the course of training. While this is analytically motivated for convex optimizations, it may not be ideal for non-convex problems. ‘RMSProp’ deals with this heuristically by allowing the learning rates to rebound as the denominator decays over time.

Define the Root Mean Square (RMS) error criterion of the gradient as :math:`\text{RMS}[g]_t = \sqrt{\text{E}[g^2]_t + \epsilon}`, where :math:`g` represents gradient and :math:`\text{E}[g^2]_t` is the decaying average over past squared gradient.
The $E[g^2]_t$ is given by:
\[
E[g^2]_t = \gamma * E[g^2]_{t-1} + (1-\gamma) * g_t^2
\]
The update step is
\[
\theta_{t+1} = \theta_t - \frac{\eta}{\text{RMS}[g]_t} g_t
\]
Hinton suggests the momentum term $\gamma$ to be 0.9 and the learning rate $\eta$ to be 0.001.
Defined in src/operator/optimizer_op.cc:1797

Value
out The result mx.symbol

mx.symbol.RNN

**RNN**: Applies recurrent layers to input data. Currently, vanilla RNN, LSTM and GRU are implemented, with both multi-layer and bidirectional support.

Description
When the input data is of type float32 and the environment variables MXNET_CUDA_ALLOW_TENSOR_CORE and MXNET_CUDA_TENSOR_OP_MATH_ALLOW_CONVERSION are set to 1, this operator will try to use pseudo-float16 precision (float32 math with float16 I/O) precision in order to use Tensor Cores on suitable NVIDIA GPUs. This can sometimes give significant speedups.

Usage

mx.symbol.RNN(...)

Arguments

data NDArray-or-Symbol Input data to RNN
parameters NDArray-or-Symbol Vector of all RNN trainable parameters concatenated
state NDArray-or-Symbol initial hidden state of the RNN
state.cell NDArray-or-Symbol initial cell state for LSTM networks (only for LSTM)
sequence.length NDArray-or-Symbol Vector of valid sequence lengths for each element in batch. (Only used if use_sequence_length kwarg is True)
state.size int (non-negative), required size of the state for each layer
num.layers int (non-negative), required number of stacked layers
bidirectional boolean, optional, default=0 whether to use bidirectional recurrent layers
mode 'gru', 'lstm', 'rnn_relu', 'rnn_tanh', required the type of RNN to compute
Vanilla RNN

Applies a single-gate recurrent layer to input X. Two kinds of activation function are supported: ReLU and Tanh.

With ReLU activation function:

.. math:: h_t = \text{relu}(W_{ih} x_t + b_{ih} + W_{hh} h_{(t-1)} + b_{hh})

With Tanh activation function:

.. math:: h_t = \tanh(W_{ih} x_t + b_{ih} + W_{hh} h_{(t-1)} + b_{hh})

**LSTM**

.. math:: \begin{array}{ll}
i_t &= \text{tanh}(W_{ii} x_t + b_{ii} + W_{ri} r_{(t-1)} + b_{ri}) \\
i_f &= \text{tanh}(W_{if} x_t + b_{if} + W_{rf} r_{(t-1)} + b_{rf}) \\
i_o &= \text{tanh}(W_{io} x_t + b_{io} + W_{ro} r_{(t-1)} + b_{ro}) \\
i_c &= f_t * c_{(t-1)} + i_t * g_t \\
h_t &= o_t * \tanh(c_t) \\
r_t &= W_{hr} h_t \end{array}

With the projection size being set, LSTM could use the projection feature to reduce the parameters size and give some speedups without significant damage to the accuracy.

.. math:: \begin{array}{ll}
i_t &= \text{tanh}(W_{ii} x_t + b_{ii} + W_{ri} r_{(t-1)} + b_{ri}) \\
i_f &= \text{tanh}(W_{if} x_t + b_{if} + W_{rf} r_{(t-1)} + b_{rf}) \\
i_o &= \text{tanh}(W_{io} x_t + b_{io} + W_{ro} r_{(t-1)} + b_{ro}) \\
i_c &= f_t * c_{(t-1)} + i_t * g_t \\
h_t &= o_t * \tanh(c_t) \\
r_t &= W_{hr} h_t \end{array}
**GRU**

The definition of GRU here is slightly different from paper but compatible with CUDNN.

```
.. math::
   r_t = \mathrm{sigmoid}(W_{ir} x_t + b_{ir} + W_{hr} h_{(t-1)} + b_{hr}) \z_t =
   \mathrm{sigmoid}(W_{iz} x_t + b_{iz} + W_{hz} h_{(t-1)} + b_{hz}) \n_t = \tanh(W_{in} x_t + b_{in} + r_t * (W_{hn} h_{(t-1)}+ b_{hn})) \h_t = (1 - z_t) * n_t + z_t * h_{(t-1)}
```

Defined in `src/operator/rnn.cc:L369`

Value

out The result `mx.symbol`

---

**mx.symbol.ROIPooling**

`ROIPooling`: Performs region of interest(ROI) pooling on the input array.

Description

ROI pooling is a variant of a max pooling layer, in which the output size is fixed and region of interest is a parameter. Its purpose is to perform max pooling on the inputs of non-uniform sizes to obtain fixed-size feature maps. ROI pooling is a neural-net layer mostly used in training a ‘Fast R-CNN’ network for object detection.

Usage

`mx.symbol.ROIPooling(...)`

Arguments

data NDArray-or-Symbol The input array to the pooling operator, a 4D Feature maps

rois NDArray-or-Symbol Bounding box coordinates, a 2D array of [[batch_index, x1, y1, x2, y2]], where (x1, y1) and (x2, y2) are top left and bottom right corners of designated region of interest. ‘batch_index’ indicates the index of corresponding image in the input array

pooled.size Shape(tuple), required ROI pooling output shape (h,w)

spatial.scale float, required Ratio of input feature map height (or w) to raw image height (or w). Equals the reciprocal of total stride in convolutional layers

name string, optional Name of the resulting symbol.
Details

This operator takes a 4D feature map as an input array and region proposals as ‘rois’, then it pools over sub-regions of input and produces a fixed-sized output array regardless of the ROI size.

To crop the feature map accordingly, you can resize the bounding box coordinates by changing the parameters ‘rois’ and ‘spatial_scale’.

The cropped feature maps are pooled by standard max pooling operation to a fixed size output indicated by a ‘pooled_size’ parameter. batch_size will change to the number of region bounding boxes after ‘ROIPooling’.

The size of each region of interest doesn’t have to be perfectly divisible by the number of pooling sections('pooled_size').

Example::

```plaintext
// region of interest i.e. bounding box coordinates. y = [[0,0,0,4,4]]
// returns array of shape (2,2) according to the given roi with max pooling. ROIPooling(x, y, (2,2), 1.0) = [[[ 14., 16.], [ 26., 28.]]]
// region of interest is changed due to the change in ‘spacial_scale’ parameter. ROIPooling(x, y, (2,2), 0.7) = [[[ 7., 9.], [ 19., 21.]]]
Defined in src/operator/roi_pooling.cc:L225
```

Value

out The result mx.symbol

mx.symbol.round

round:Returns element-wise rounded value to the nearest integer of the input.

Description

Example::

Usage

mx.symbol.round(...)

Arguments

data NDArray-or-Symbol The input array.

name string, optional Name of the resulting symbol.
Details

\[
\text{round}([-1.5, 1.5, -1.9, 1.9, 2.1]) = [-2., 2., -2., 2., 2.]
\]
The storage type of “round” output depends upon the input storage type:
- round(default) = default - round(row_sparse) = row_sparse - round(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L777

Value

out The result mx.symbol

mx.symbol.rsqrtr

rsqrt: Returns element-wise inverse square-root value of the input.

Description

.. math:: \text{rsqrt}(x) = \frac{1}{\sqrt{x}}

Usage

mx.symbol.rsqrt(...)

Arguments

data NDArray-or-Symbol The input array.
name string, optional Name of the resulting symbol.

Details

Example::

    \text{rsqrt}([4,9,16]) = [0.5, 0.33333334, 0.25]
The storage type of “rsqrt” output is always dense

Defined in src/operator/tensor/elemwise_unary_op_pow.cc:L221

Value

out The result mx.symbol
**mx.symbol.sample_exponential**

`sample_exponential`: Concurrent sampling from multiple exponential distributions with parameters lambda (rate).

**Description**

The parameters of the distributions are provided as an input array. Let *s* be the shape of the input array, *n* be the dimension of *s*, *t* be the shape specified as the parameter of the operator, and *m* be the dimension of *t*. Then the output will be a *(n+m)*-dimensional array with shape *s* x *t*.

**Usage**

```python
mx.symbol.sample_exponential(...)```

**Arguments**

- **lam**: NDArray-or-Symbol. Lambda (rate) parameters of the distributions.
- **shape**: Shape(tuple), optional, default=[]. Shape to be sampled from each random distribution.
- **dtype**: 'None', 'float16', 'float32', 'float64', optional, default='None'. Dtype of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).
- **name**: string, optional. Name of the resulting symbol.

**Details**

For any valid *n*-dimensional index *i* with respect to the input array, *output[i]* will be an *(n+m)*-dimensional array that holds randomly drawn samples from the distribution which is parameterized by the input value at index *i*. If the shape parameter of the operator is not set, then one sample will be drawn per distribution and the output array has the same shape as the input array.

**Examples**:

```python
lam = [ 1.0, 8.5 ]
// Draw a single sample for each distribution sample_exponential(lam) = [ 0.51837951, 0.09994757]
// Draw a vector containing two samples for each distribution sample_exponential(lam, shape=(2)) = [[ 0.51837951, 0.19866663], [ 0.09994757, 0.50447971]]
```

**Value**

```python
out The result mx.symbol```

Defined in `src/operator/random/multisample_op.cc:L284`
mx.symbol.sample_gamma

**sample_gamma:** Concurrent sampling from multiple gamma distributions with parameters *alpha* (shape) and *beta* (scale).

**Description**

The parameters of the distributions are provided as input arrays. Let *[s]* be the shape of the input arrays, *n* be the dimension of *[s]*, *[t]* be the shape specified as the parameter of the operator, and *m* be the dimension of *[t]*. Then the output will be a *(n+m)*-dimensional array with shape *[s]x[t]*.

**Usage**

```python
mx.symbol.sample_gamma(...)
```

**Arguments**

- **alpha**: NDArray-or-Symbol Alpha (shape) parameters of the distributions.
- **shape**: Shape(tuple), optional, default=[] Shape to be sampled from each random distribution.
- **dtype**: 'None', 'float16', 'float32', 'float64', optional, default='None' DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).
- **beta**: NDArray-or-Symbol Beta (scale) parameters of the distributions.
- **name**: string, optional Name of the resulting symbol.

**Details**

For any valid *n* dimensional index *i* with respect to the input arrays, *output[i]* will be an *m* dimensional array that holds randomly drawn samples from the distribution which is parameterized by the input values at index *i*. If the shape parameter of the operator is not set, then one sample will be drawn per distribution and the output array has the same shape as the input arrays.

**Examples**:

```python
alpha = [ 0.0, 2.5 ] beta = [ 1.0, 0.7 ]
// Draw a single sample for each distribution sample_gamma(alpha, beta) = [ 0. , 2.25797319]
// Draw a vector containing two samples for each distribution sample_gamma(alpha, beta, shape=(2))
= [[ 0. , 0. ], [ 2.25797319, 1.70734084]]
```

Defined in src/operator/random/multisample_op.cc:L282

**Value**

```python
out The result mx.symbol
```
mx.symbol.sample_generalized_negative_binomial

*sample_generalized_negative_binomial*: Concurrent sampling from multiple generalized negative binomial distributions with parameters *mu* (mean) and *alpha* (dispersion).

Description

The parameters of the distributions are provided as input arrays. Let *[s]* be the shape of the input arrays, *n* be the dimension of *[s]*, *[t]* be the shape specified as the parameter of the operator, and *m* be the dimension of *[t]*. Then the output will be a *(n+m)*-dimensional array with shape *[s]*x*[t]*.

Usage

mx.symbol.sample_generalized_negative_binomial(...)

Arguments

- **mu**: NDArray-or-Symbol Means of the distributions.
- **shape**: Shape(tuple), optional, default=[] Shape to be sampled from each random distribution.
- **dtype**: 'None', 'float16', 'float32', 'float64', optional, default='None' DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).
- **alpha**: NDArray-or-Symbol Alpha (dispersion) parameters of the distributions.
- **name**: string, optional Name of the resulting symbol.

Details

For any valid *n*-dimensional index *i* with respect to the input arrays, *output*[i] will be an *m*-dimensional array that holds randomly drawn samples from the distribution which is parameterized by the input values at index *i*. If the shape parameter of the operator is not set, then one sample will be drawn per distribution and the output array has the same shape as the input arrays.

Samples will always be returned as a floating point data type.

Examples::

mu = [ 2.0, 2.5 ] alpha = [ 1.0, 0.1 ]

// Draw a single sample for each distribution sample_generalized_negative_binomial(mu, alpha) = [ 0., 3. ]

// Draw a vector containing two samples for each distribution sample_generalized_negative_binomial(mu, alpha, shape=(2)) = [[ 0., 3.], [ 3., 1.]]

Defined in src/operator/random/multisample_op.cc:L293

Value

out The result mx.symbol
The `mx.symbol.sample_multinomial` function allows for concurrent sampling from multiple multinomial distributions.

**Description**

`data` is an `n` dimensional array whose last dimension has length `k`, where `k` is the number of possible outcomes of each multinomial distribution. This operator will draw `shape` samples from each distribution. If `shape` is empty one sample will be drawn from each distribution.

**Usage**

```python
mx.symbol.sample_multinomial(...)```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>data</code></td>
<td>NDArray-or-Symbol Distribution probabilities. Must sum to one on the last axis.</td>
</tr>
<tr>
<td><code>shape</code></td>
<td>Shape(tuple), optional, default=[] Shape to be sampled from each random distribution.</td>
</tr>
<tr>
<td><code>get.prob</code></td>
<td>boolean, optional, default=0 Whether to also return the log probability of sampled result. This is usually used for differentiating through stochastic variables, e.g. in reinforcement learning.</td>
</tr>
<tr>
<td><code>dtype</code></td>
<td>'float16', 'float32', 'float64', 'int32', 'uint8', optional, default='int32' DType of the output in case this can’t be inferred.</td>
</tr>
<tr>
<td><code>name</code></td>
<td>string, optional Name of the resulting symbol.</td>
</tr>
</tbody>
</table>

**Details**

If `get_prob` is true, a second array containing log likelihood of the drawn samples will also be returned. This is usually used for reinforcement learning where you can provide reward as head gradient for this array to estimate gradient.

Note that the input distribution must be normalized, i.e. `data` must sum to 1 along its last axis.

**Examples**

```python
probs = [[0.0, 0.1, 0.2, 0.3, 0.4], [0.4, 0.3, 0.2, 0.1, 0.0]]
// Draw a single sample for each distribution
sample_multinomial(probs) = [3, 0]
// Draw a vector containing two samples for each distribution
sample_multinomial(probs, shape=(2)) = [[4, 2], [0, 0]]
// requests log likelihood
sample_multinomial(probs, get_prob=True) = [2, 1], [0.2, 0.3]
```

**Value**

`out` The result `mx.symbol`
mx.symbol.sample_negative_binomial

**sample_negative_binomial:** Concurrent sampling from multiple negative binomial distributions with parameters *k* (failure limit) and *p* (failure probability).

### Description

The parameters of the distributions are provided as input arrays. Let *[s]* be the shape of the input arrays, *[n]* be the dimension of *[s]*, *[t]* be the shape specified as the parameter of the operator, and *[m]* be the dimension of *[t]*. Then the output will be a *(n+m)*-dimensional array with shape *[s]*<x>*[t]*

### Usage

```python
mx.symbol.sample_negative_binomial(...)
```

### Arguments

- **k**
  - **NDArray-or-Symbol**
  - Limits of unsuccessful experiments.

- **shape**
  - **Shape(tuple), optional, default=[]**
  - Shape to be sampled from each random distribution.

- **dtype**
  - `'None', 'float16', 'float32', 'float64'`, optional, default='None'
  - Dtype of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).

- **p**
  - **NDArray-or-Symbol**
  - Failure probabilities in each experiment.

- **name**
  - **string, optional**
  - Name of the resulting symbol.

### Details

For any valid *[n]*-dimensional index *[i]* with respect to the input arrays, *[output][i]* will be an *[m]*-dimensional array that holds randomly drawn samples from the distribution which is parameterized by the input values at index *[i]*. If the shape parameter of the operator is not set, then one sample will be drawn per distribution and the output array has the same shape as the input arrays.

Samples will always be returned as a floating point data type.

**Examples:**

```python
k = [20, 49] p = [0.4, 0.77]
// Draw a single sample for each distribution
sample_negative_binomial(k, p) = [15., 16.]
// Draw a vector containing two samples for each distribution
sample_negative_binomial(k, p, shape=(2)) = [[15., 50.], [16., 12.]]
```

Defined in `src/operator/random/multisample_op.cc:L289`

### Value

- **out**
  - The result mx.symbol
mx.symbol.sample_normal

(sample_normal): Concurrent sampling from multiple normal distributions with parameters \( \mu \) (mean) and \( \sigma \) (standard deviation).

Description

The parameters of the distributions are provided as input arrays. Let \([s]\)* be the shape of the input arrays, \(n\)* be the dimension of \([s]\)*, \([t]\)* be the shape specified as the parameter of the operator, and \(m\)* be the dimension of \([t]\)*. Then the output will be a \((n+m)\)*-dimensional array with shape \([s]\times[t]\)*.

Usage

mx.symbol.sample_normal(...)

Arguments

- **mu**: NDArray-or-Symbol Means of the distributions.
- **shape**: Shape(tuple), optional, default=[] Shape to be sampled from each random distribution.
- **dtype**: 'None', 'float16', 'float32', 'float64', optional, default='None' Dtype of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).
- **sigma**: NDArray-or-Symbol Standard deviations of the distributions.
- **name**: string, optional Name of the resulting symbol.

Details

For any valid \(n\)*-dimensional index \(i\)* with respect to the input arrays, \(output[i]\)* will be an \(m\)*-dimensional array that holds randomly drawn samples from the distribution which is parameterized by the input values at index \(i\)*. If the shape parameter of the operator is not set, then one sample will be drawn per distribution and the output array has the same shape as the input arrays.

Examples:

```python
mu = [ 0.0, 2.5 ] sigma = [ 1.0, 3.7 ]
// Draw a single sample for each distribution
sample_normal(mu, sigma) = [-0.56410581, 0.95934606]
// Draw a vector containing two samples for each distribution
sample_normal(mu, sigma, shape=(2)) = [[-0.56410581, 0.2928229], [0.95934606, 4.48287058]]
```

Defined in src/operator/random/multisample_op.cc:L279

Value

out The result mx.symbol
mx.symbol.sample_poisson

sample_poisson: Concurrent sampling from multiple Poisson distributions with parameters lambda (rate).

Description

The parameters of the distributions are provided as an input array. Let *[s]* be the shape of the input array, *n* be the dimension of *[s]*, *[t]* be the shape specified as the parameter of the operator, and *m* be the dimension of *[t]*. Then the output will be a *(n+m)*-dimensional array with shape *[s]*x*[t]*.

Usage

mx.symbol.sample_poisson(...)

Arguments

lam
NDArray-or-Symbol Lambda (rate) parameters of the distributions.

shape
Shape(tuple), optional, default=[] Shape to be sampled from each random distribution.

dtype
‘None’, ‘float16’, ‘float32’, ‘float64’,optional, default=’None’ DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).

name
string, optional Name of the resulting symbol.

Details

For any valid *n*-dimensional index *i* with respect to the input array, *output[i]* will be an *m*-dimensional array that holds randomly drawn samples from the distribution which is parameterized by the input value at index *i*. If the shape parameter of the operator is not set, then one sample will be drawn per distribution and the output array has the same shape as the input array.

Samples will always be returned as a floating point data type.

Examples:

```python
lam = [ 1.0, 8.5 ]
// Draw a single sample for each distribution sample_poisson(lam) = [ 0., 13. ]
// Draw a vector containing two samples for each distribution sample_poisson(lam, shape=(2)) = [[ 0., 4.], [ 13., 8. ]]
```

Defined in src/operator/random/multisample_op.cc:L286

Value

out The result mx.symbol
mx.symbol.sample_uniform

sample_uniform: Concurrent sampling from multiple uniform distributions on the intervals given by *(low,high)*.

Description

The parameters of the distributions are provided as input arrays. Let *s* be the shape of the input arrays, *n* be the dimension of *s*, *t* be the shape specified as the parameter of the operator, and *m* be the dimension of *t*. Then the output will be an *(n+m)*-dimensional array with shape *s x t*.

Usage

mx.symbol.sample_uniform(...)

Arguments

- **low**: NDArray-or-Symbol Lower bounds of the distributions.
- **shape**: Shape(tuple), optional, default=[] Shape to be sampled from each random distribution.
- **dtype**: 'None', 'float16', 'float32', 'float64', optional, default='None' DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).
- **high**: NDArray-or-Symbol Upper bounds of the distributions.
- **name**: string, optional Name of the resulting symbol.

Details

For any valid *n*-dimensional index *i* with respect to the input arrays, *output[i]* will be an *m*-dimensional array that holds randomly drawn samples from the distribution which is parameterized by the input values at index *i*. If the shape parameter of the operator is not set, then one sample will be drawn per distribution and the output array has the same shape as the input arrays.

Examples:

```python
low = [ 0.0, 2.5 ]
high = [ 1.0, 3.7 ]

# Draw a single sample for each distribution
sample_uniform(low, high) = [ 0.40451524, 3.18687344]

# Draw a vector containing two samples for each distribution
sample_uniform(low, high, shape=(2)) = [[ 0.40451524, 0.18017688], [ 3.18687344, 3.68352246]]
```

Defined in src/operator/random/multisample_op.cc:L277

Value

out The result mx.symbol
mx.symbol.save

Save an mx.symbol object

Description

Save an mx.symbol object

Usage

mx.symbol.save(symbol, filename)

Arguments

symbol            the mx.symbol object
filename          the filename (including the path)

Examples

data = mx.symbol.Variable('data')
mx.symbol.save(data, 'temp.symbol')
data2 = mx.symbol.load('temp.symbol')

mx.symbol.scatter_nd

scatter_nd: Scatters data into a new tensor according to indices.

Description

Given 'data' with shape '(Y_0, ..., Y_K-1, X_M, ..., X_N-1)' and indices with shape '(M, Y_0, ..., Y_K-1)', the output will have shape '(X_0, X_1, ..., X_N-1)', where 'M <= N'. If 'M == N', data shape should simply be '(Y_0, ..., Y_K-1)'.

Usage

mx.symbol.scatter_nd(...)

Arguments

data                NDArray-or-Symbol data
indices             NDArray-or-Symbol indices
shape               Shape(tuple), required Shape of output.
name                string, optional Name of the resulting symbol.
Details

The elements in output is defined as follows:

\[
\text{output}[\text{indices}[0, y_0, ..., y_K-1], ..., \text{indices}[M-1, y_0, ..., y_K-1], x_M, ..., x_N-1] = \text{data}[y_0, ..., y_K-1, x_M, ..., x_N-1]
\]

all other entries in output are 0.

.. warning::

If the indices have duplicates, the result will be non-deterministic and the gradient of `scatter_nd` will not be correct!!

Examples:

\[
data = [2, 3, 0] \text{ indices } = [[1, 1, 0], [0, 1, 0]] \text{ shape } = (2, 2) \text{ scatter}_\text{nd}(\text{data}, \text{indices}, \text{shape}) = [[0, 0], [2, 3]]
\]

\[
data = [[[1, 2], [3, 4]], [[5, 6], [7, 8]]] \text{ indices } = [[0, 1], [1, 1]] \text{ shape } = (2, 2, 2, 2) \text{ scatter}_\text{nd}(\text{data}, \text{indices}, \text{shape}) = [[[0, 0], [0, 0]], [[1, 2], [3, 4]], [[0, 0], [0, 0]], [[5, 6], [7, 8]]]
\]

Value

out The result mx.symbol

mx.symbol.SequenceLast

SequenceLast: Takes the last element of a sequence.

Description

This function takes an n-dimensional input array of the form \([\text{max_sequence_length}, \text{batch_size}, \text{other_feature_dims}]\) and returns a \((n-1)\)-dimensional array of the form \([\text{batch_size}, \text{other_feature_dims}]\).

Usage

mx.symbol.SequenceLast(…)

Arguments

data NDArray-or-Symbol n-dimensional input array of the form \([\text{max_sequence_length}, \text{batch_size}, \text{other_feature_dims}]\) where \(n>2\)

sequence_length NDArray-or-Symbol vector of sequence lengths of the form \([\text{batch_size}]\)

use.sequence.length boolean, optional, default=0 If set to true, this layer takes in an extra input parameter `sequence_length` to specify variable length sequence
SequenceMask

**Description**

This function takes an n-dimensional input array of the form `[max_sequence_length, batch_size, other_feature_dims]` and returns an array of the same shape.

**Usage**

```python
mx.symbol.SequenceMask(...)
```
Arguments

data
NDArray-or-Symbol n-dimensional input array of the form [max_sequence_length, batch_size, other_feature_dims] where n>2

sequence.length
NDArray-or-Symbol vector of sequence lengths of the form [batch_size]

use.sequence.length
boolean, optional, default=0 If set to true, this layer takes in an extra input parameter ‘sequence_length’ to specify variable length sequence

value
float, optional, default=0 The value to be used as a mask.

axis
int, optional, default='0' The sequence axis. Only values of 0 and 1 are currently supported.

name
string, optional Name of the resulting symbol.

Details

Parameter ‘sequence_length’ is used to handle variable-length sequences. ‘sequence_length’ should be an input array of positive ints of dimension [batch_size]. To use this parameter, set ‘use_sequence_length’ to ‘True’, otherwise each example in the batch is assumed to have the max sequence length and this operator works as the ‘identity’ operator.

Example::

x = [[[ 1., 2., 3.], [ 4., 5., 6.]],
[[ 7., 8., 9.], [10., 11., 12.]],
[[13., 14., 15.], [16., 17., 18.]]]

// Batch 1 B1 = [[[ 1., 2., 3.], [ 7., 8., 9.], [13., 14., 15.]]

// works as identity operator when sequence_length parameter is not used SequenceMask(x) = [[[ 1., 2., 3.], [ 4., 5., 6.]],
[[ 7., 8., 9.], [10., 11., 12.]],
[[13., 14., 15.], [16., 17., 18.]]]

// sequence_length [1,1] means 1 of each batch will be kept // and other rows are masked with default mask value = 0 SequenceMask(x, sequence_length=[1,1], use_sequence_length=True) = [[[ 1., 2., 3.], [ 4., 5., 6.]],
[[ 0., 0., 0.], [ 0., 0., 0.]],
[[ 0., 0., 0.], [ 0., 0., 0.]]]

// sequence_length [2,3] means 2 of batch B1 and 3 of batch B2 will be kept // and other rows are masked with value = 1 SequenceMask(x, sequence_length=[2,3], use_sequence_length=True, value=1) = [[[ 1., 2., 3.], [ 4., 5., 6.]],
[[ 7., 8., 9.], [10., 11., 12.]],
[[ 1., 1., 1.], [16., 17., 18.]]]

Defined in src/operator/sequence_mask.cc:L186
mx.symbol.SequenceReverse

Value
out The result mx.symbol

mx.symbol.SequenceReverse

SequenceReverse: Reverses the elements of each sequence.

Description
This function takes an n-dimensional input array of the form [max_sequence_length, batch_size, other_feature_dims] and returns an array of the same shape.

Usage
mx.symbol.SequenceReverse(...)

Arguments
- **data**: NDArray-or-Symbol n-dimensional input array of the form [max_sequence_length, batch_size, other dims] where n>2
- **sequence_length**: NDArray-or-Symbol vector of sequence lengths of the form [batch_size]
- **use_sequence_length**: boolean, optional, default=0 If set to true, this layer takes in an extra input parameter 'sequence_length' to specify variable length sequence
- **axis**: int, optional, default='0' The sequence axis. Only 0 is currently supported.
- **name**: string, optional Name of the resulting symbol.

Details
Parameter ‘sequence_length’ is used to handle variable-length sequences. ‘sequence_length’ should be an input array of positive ints of dimension [batch_size]. To use this parameter, set ‘use_sequence_length’ to ‘True’, otherwise each example in the batch is assumed to have the max sequence length.

Example:
x = [[[ 1., 2., 3.], [ 4., 5., 6.]],
     [[ 7., 8., 9.], [ 10., 11., 12.]],
     [[ 13., 14., 15.], [ 16., 17., 18.]]]

// Batch 1 B1 = [[[ 1., 2., 3.], [ 7., 8., 9.], [ 13., 14., 15.]]

// returns reverse sequence when sequence_length parameter is not used SequenceReverse(x) = [[[ 13., 14., 15.], [ 16., 17., 18.]],
     [[ 7., 8., 9.], [ 10., 11., 12.]],
     [[ 1., 2., 3.], [ 4., 5., 6.]]]
// sequence_length [2,2] means 2 rows of // both batch B1 and B2 will be reversed. SequenceRe-
verse(x, sequence_length=[2,2], use_sequence_length=True) = [[[ 7., 8., 9.], [ 10., 11., 12.]],
[[ 13., 14., 15.], [ 16., 17., 18.]]
// sequence_length [2,3] means 2 of batch B2 and 3 of batch B3 // will be reversed. SequenceRe-
verse(x, sequence_length=[2,3], use_sequence_length=True) = [[[ 7., 8., 9.], [ 16., 17., 18.]],
[[ 1., 2., 3.], [ 10., 11., 12.]],
[[ 13., 14, 15.], [ 4., 5., 6.]]
Defined in src/operator/sequence_reverse.cc:L122

dgd_mom_update: Momentum update function for Stochastic Gradient Descent (SGD) optimizer.

Description

Momentum update has better convergence rates on neural networks. Mathematically it looks like below:

Usage

mx.symbol.sgd_mom_update(...)
Details
.. math::
\begin{align*}
v_{1} &= \alpha * \nabla J(W_{0}) \quad v_{t} = \gamma v_{t-1} - \alpha * \nabla J(W_{t-1}) \\
W_{t} &= W_{t-1} + v_{t}
\end{align*}
It updates the weights using::
\begin{align*}
v &= \text{momentum} * v - \text{learning}_\text{rate} * \text{gradient} \\
\text{weight} &\text{+= v}
\end{align*}
Where the parameter "momentum" is the decay rate of momentum estimates at each epoch.
However, if grad’s storage type is “row_sparse”, “lazy_update” is True and weight’s storage type is the same as momentum’s storage type, only the row slices whose indices appear in grad.indices are updated (for both weight and momentum)::
\begin{align*}
\text{weight[row] &+= v[row]}
\end{align*}
Defined in src/operator/optimizer_op.cc:L565

Value
out The result mx.symbol

mx.symbol.sgd_update

\textit{sgd\_update}: \textit{Update function for Stochastic Gradient Descent (SGD) optimizer.}

Description
It updates the weights using::

Usage
mx.symbol.sgd_update(...)

Arguments
weight NDArray-or-Symbol Weight
grad NDArray-or-Symbol Gradient
lr float, required Learning rate
wd float, optional, default=0 Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
rescale.grad float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
clip.gradient float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient]
If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).
lazy.update boolean, optional, default=1 If true, lazy updates are applied if gradient’s stype is row_sparse.
name string, optional Name of the resulting symbol.
weight = weight - learning_rate * (gradient + wd * weight)

However, if gradient is of “row_sparse” storage type and “lazy_update” is True, only the row slices whose indices appear in grad.indices are updated:

Defined in src/operator/optimizer_op.cc:L524

Value

out The result mx.symbol

mx.symbol.shape_array

shape_array: Returns a 1D int64 array containing the shape of data.

Description

Example::

Usage

mx.symbol.shape_array(...)

Arguments

data NDArray-or-Symbol Input Array.

name string, optional Name of the resulting symbol.

Details

shape_array([[1,2,3,4], [5,6,7,8]]) = [2,4]

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L573

Value

out The result mx.symbol
mx.symbol.shuffle  

shuffle: Randomly shuffle the elements.

Description

This shuffles the array along the first axis. The order of the elements in each subarray does not change. For example, if a 2D array is given, the order of the rows randomly changes, but the order of the elements in each row does not change.

Usage

mx.symbol.shuffle(...)

Arguments

data  NDArray-or-Symbol Data to be shuffled.
name  string, optional Name of the resulting symbol.

Value

out The result mx.symbol

mx.symbol.sigmoid  
sigmoid: Computes sigmoid of x element-wise.

Description

.. math:: y = 1 / (1 + \exp(-x))

Usage

mx.symbol.sigmoid(...)

Arguments

data  NDArray-or-Symbol The input array.
name  string, optional Name of the resulting symbol.

Details

The storage type of "sigmoid" output is always dense
Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L119

Value

out The result mx.symbol
Description

Example::

Usage

mx.symbol.sign(...)

Arguments

data NDArray-or-Symbol The input array.
name string, optional Name of the resulting symbol.

Details

sign([-2, 0, 3]) = [-1, 0, 1]
The storage type of “sign” output depends upon the input storage type:
- sign(default) = default - sign(row_sparse) = row_sparse - sign(csr) = csr
Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L758

Value

out The result mx.symbol

Description

Usage

mx.symbol.signsgd_update(...)

signsgd_update: Update function for SignSGD optimizer.
Arguments

- **weight** : NDArray-or-Symbol Weight
- **grad** : NDArray-or-Symbol Gradient
- **lr** : float, required Learning rate
- **wd** : float, optional, default=0 Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
- **rescale.grad** : float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
- **clip.gradient** : float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient]. If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).
- **name** : string, optional Name of the resulting symbol.

Details

\[ g_t = \nabla J(W_{t-1}) \]  
\[ W_t = W_{t-1} - \eta_t \text{sign}(g_t) \]

It updates the weights using::

weight = weight - learning_rate * sign(gradient)

.. note:: - sparse ndarray not supported for this optimizer yet.

Defined in src/operator/optimizer_op.cc:L63

Value

out The result mx.symbol

Description

.. math::

Usage

mx.symbol.signum_update(...)

mx.symbol.signum_update

signum_update:SIGN momentUM (Signum) optimizer.
Arguments

weight NDArray-or-Symbol Weight
grad NDArray-or-Symbol Gradient
mom NDArray-or-Symbol Momentum
lr float, required Learning rate
momentum float, optional, default=0 The decay rate of momentum estimates at each epoch.
wd float, optional, default=0 Weight decay augments the objective function with a regularization term that penalizes large weights. The penalty scales with the square of the magnitude of each weight.
rescale.grad float, optional, default=1 Rescale gradient to grad = rescale_grad*grad.
clip.gradient float, optional, default=-1 Clip gradient to the range of [-clip_gradient, clip_gradient]

Clip gradient to the range of [-clip_gradient, clip_gradient]
If clip_gradient <= 0, gradient clipping is turned off. grad = max(min(grad, clip_gradient), -clip_gradient).
wd.lh float, optional, default=0 The amount of weight decay that does not go into gradient/momentum calculationsotherwise do weight decay algorithmically only.
name string, optional Name of the resulting symbol.

Details

g_t = \nabla J(W_{t-1})
m_t = \beta m_{t-1} + (1 - \beta) g_t
W_t = W_{t-1} - \eta_t \text{sign}(m_t)
It updates the weights using::
state = momentum * state + (1-momentum) * gradient
weight = weight - learning_rate * sign(state)

Where the parameter “momentum“ is the decay rate of momentum estimates at each epoch.

.. note:: - sparse ndarray not supported for this optimizer yet.
Defined in src/operator/optimizer_op.cc:L92

Value

out The result mx.symbol

mx.symbol.sin

sin:Computes the element-wise sine of the input array.

Description

The input should be in radians (:math:`\text{’2\pi’}` rad equals 360 degrees).

Usage

mx.symbol.sin(…)
mx.symbol.sinh

Arguments

- **data**: NDArray-or-Symbol The input array.
- **name**: string, optional Name of the resulting symbol.

Details

.. math:: \sin([0, \pi/4, \pi/2]) = [0, 0.707, 1]

The storage type of “sin” output depends upon the input storage type:
- sin(default) = default - sin(row_sparse) = row_sparse - sin(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L47

Value

- out The result mx.symbol

mx.symbol.sinh

.. Returns the hyperbolic sine of the input array, computed element-wise.

Description

.. math:: \sinh(x) = 0.5 \times (\exp(x) - \exp(-x))

Usage

mx.symbol.sinh(...)

Arguments

- **data**: NDArray-or-Symbol The input array.
- **name**: string, optional Name of the resulting symbol.

Details

The storage type of “sinh” output depends upon the input storage type:
- sinh(default) = default - sinh(row_sparse) = row_sparse - sinh(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L371

Value

- out The result mx.symbol
mx.symbol.size_array

size_array: Returns a 1D int64 array containing the size of data.

Description

Example::

Usage

mx.symbol.size_array(...)

Arguments

data NDArray-or-Symbol Input Array.

name string, optional Name of the resulting symbol.

Details

size_array([[1,2,3,4], [5,6,7,8]]) = [8]

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L624

Value

out The result mx.symbol
mx.symbol.slice
text:
slice:Slices a region of the array. .. note:: “crop” is deprecated. Use “slice” instead. This function returns a sliced array between the indices given by ‘begin’ and ‘end’ with the corresponding ‘step’. For an input array of “shape=(d_0, d_1, ..., d_n-1)”, slice operation with “begin=(b_0, b_1, ..., b_m-1)”, “end=(e_0, e_1, ..., e_m-1)”, and “step=(s_0, s_1, ..., s_m-1)”, where m <= n, results in an array with the shape “(|e_0-b_0|/|s_0|, ..., |e_m-1-b_m-1|/|s_m-1|, d_m, ..., d_n-1)”. The resulting array’s *k*-th dimension contains elements from the *k*-th dimension of the input array starting from index “b_k” (inclusive) with step “s_k” until reaching “e_k” (exclusive). If the *k*-th elements are ‘None’ in the sequence of ‘begin’, ‘end’, and ‘step’, the following rule will be used to set default values. If ‘s_k’ is ‘None’, set ‘s_k=1’. If ‘s_k > 0’, set ‘b_k=0’, ‘e_k=d_k’; else, set ‘b_k=d_k-1’, ‘e_k=-1’. The storage type of “slice” output depends on storage types of inputs - slice(csr) = csr - otherwise, “slice” generates output with default storage .. note:: When input data storage type is csr, it only supports step=(), or step=(None,), or step=(1,) to generate a csr output. For other step parameter values, it falls back to slicing a dense tensor. Example:: x = \[
[ 1., 2., 3., 4.],
[ 5., 6., 7., 8.],
[ 9., 10., 11., 12.]
\] slice(x, begin=(0,1), end=(2,4)) = \[
[ 2., 3., 4.],
[ 6., 7., 8.]
\] slice(x, begin=(None, 0), end=(None, 3), step=(-1, 2)) = \[
[9., 11.],
[5., 7.], [1., 3.]
\]

Description
Defined in src/operator/tensor/matrix_op.cc:L482

Usage
mx.symbol.slice(...)

Arguments
data
begin
end
step
name

Value
out The result mx.symbol
mx.symbol.SliceChannel

SliceChannel: Splits an array along a particular axis into multiple sub-arrays.

Description

.. note:: “SliceChannel” is deprecated. Use “split” instead.

Usage

mx.symbol.SliceChannel(...)  

Arguments

data  
NDArray-or-Symbol The input  

num.outputs  
int, required Number of splits. Note that this should evenly divide the length of the ‘axis’.

axis  
int, optional, default=’1’ Axis along which to split.

squeeze.axis  
boolean, optional, default=0 If true, Removes the axis with length 1 from the shapes of the output arrays. **Note** that setting ‘squeeze_axis’ to “true” removes axis with length 1 only along the ‘axis’ which it is split. Also ‘squeeze_axis’ can be set to “true” only if “input.shape[axis] == num_outputs”.

name  
string, optional Name of the resulting symbol.

Details

**Note** that ‘num_outputs’ should evenly divide the length of the axis along which to split the array.

Example::

x = [[[1.] [2.]] [[3.] [4.]] [[5.] [6.]]] x.shape = (3, 2, 1)  
y = split(x, axis=1, num_outputs=2) // a list of 2 arrays with shape (3, 1, 1)  
y = [[[1.] [3.]] [[5.]]]  
y[0].shape = (3, 1, 1)  
z = split(x, axis=0, num_outputs=3) // a list of 3 arrays with shape (1, 2, 1)  
z = [[[1.] [2.]]]  
z[0].shape = (1, 2, 1)  

‘squeeze_axis=1’ removes the axis with length 1 from the shapes of the output arrays. **Note** that setting ‘squeeze_axis’ to “1” removes axis with length 1 only along the ‘axis’ which it is split. Also ‘squeeze_axis’ can be set to true only if “input.shape[axis] == num_outputs”.

Example::
\[ z = \text{split}(x, \text{axis}=0, \text{num_outputs}=3, \text{squeeze_axis}=1) \] // a list of 3 arrays with shape (2, 1) \[ z = \begin{bmatrix} 1. \\ 2. \\ 3. \\ 4. \\ 5. \\ 6. \end{bmatrix} \]
\[ z[0].\text{shape} = (2, 1) \]

Defined in src/operator/slice_channel.cc:L107

**Value**

out The result mx.symbol

---

**mx.symbol.slice_axis**

slice_axis: Slices along a given axis. Returns an array slice along a given 'axis' starting from the 'begin' index to the 'end' index. Examples::

\[ x = \begin{bmatrix} 1., 2., 3., 4. \\ 5., 6., 7., 8. \\ 9., 10., 11., 12. \end{bmatrix} \]

\[ \text{slice_axis}(x, \text{axis}=0, \text{begin}=1, \text{end}=3) = \begin{bmatrix} 5., 6., 7., 8. \\ 9., 10., 11., 12. \end{bmatrix} \]

\[ \text{slice_axis}(x, \text{axis}=1, \text{begin}=0, \text{end}=2) = \begin{bmatrix} 1., 2. \\ 5., 6. \\ 9., 10. \end{bmatrix} \]

\[ \text{slice_axis}(x, \text{axis}=1, \text{begin}=-3, \text{end}=-1) = \begin{bmatrix} 2., 3. \\ 6., 7. \\ 10., 11. \end{bmatrix} \]

**Description**

Defined in src/operator/tensor/matrix_op.cc:L571

**Usage**

\[ \text{mx.symbol.slice_axis}(...) \]

**Arguments**

- **data**: NDArray-or-Symbol Source input
- **axis**: int, required Axis along which to be sliced, supports negative indexes.
- **begin**: int, required The beginning index along the axis to be sliced, supports negative indexes.
- **end**: int or None, required The ending index along the axis to be sliced, supports negative indexes.
- **name**: string, optional Name of the resulting symbol.

**Value**

out The result mx.symbol
slice_like: Slices a region of the array like the shape of another array. This function is similar to "slice", however, the 'begin' are always 0's and 'end' of specific axes are inferred from the second input 'shape_like'. Given the second 'shape_like' input of "shape=(d_0, d_1, ..., d_n-1)", a "slice_like" operator with default empty 'axes', it performs the following operation: " out = slice(input, begin=(0, 0, ..., 0), end=(d_0, d_1, ..., d_n-1))". When 'axes' is not empty, it is used to specify which axes are being sliced. Given a 4-d input data, "slice_like" operator with "axes=(0, 2, -1)" will perform the following operation: " out = slice(input, begin=(0, 0, 0, 0), end=(d_0, None, d_2, d_3))". Note that it is allowed to have first and second input with different dimensions, however, you have to make sure the 'axes' are specified and not exceeding the dimension limits. For example, given 'input_1' with "shape=(2,3,4,5)" and 'input_2' with "shape=(1,2,3)", it is not allowed to use: " out = slice_like(a, b)" because ndim of 'input_1' is 4 and ndim of 'input_2' is 3. The following is allowed in this situation: " out = slice_like(a, b, axes=(0, 2))"

Example::

```python
x = [[1., 2., 3., 4.], [5., 6., 7., 8.], [9., 10., 11., 12.]]
y = [[0., 0., 0.], [0., 0., 0.]]
slice_like(x, y) = [[1., 2., 3.]]
slice_like(x, y, axes=(0, 1)) = [[1., 2., 3.]]
slice_like(x, y, axes=(0)) = [[1., 2., 3.], [5., 6., 7.]]
slice_like(x, y, axes=(-1)) = [[1., 2., 3.], [5., 6., 7.], [9., 10., 11.]]
```

Description
Defined in src/operator/tensor/matrix_op.cc:L625

Usage
mx.symbol.slice_like(...)

Arguments
- **data**: NDArray-or-Symbol Source input
- **shape_like**: NDArray-or-Symbol Shape like input
- **axes**: Shape(tuple), optional, default=[ ] List of axes on which input data will be sliced according to the corresponding size of the second input. By default will slice on all axes. Negative axes are supported.
- **name**: string, optional Name of the resulting symbol.

Value
- **out**: The result mx.symbol
mx.symbol.smooth_l1

smooth_l1: Calculate Smooth L1 Loss(lhs, scalar) by summing

Description

.. math::

Usage

.. code::

   mx.symbol.smooth_l1(...)

Arguments

data NDArray-or-Symbol source input
scalar float scalar input
name string, optional Name of the resulting symbol.

Details

f(x) = \begin{cases}
  (\sigma x)^2 / 2, & \text{if } x < 1 / \sigma^2 \\
  |x| - 0.5 / \sigma^2, & \text{otherwise}
\end{cases}

where :math:`x` is an element of the tensor :math:`lhs` and :math:`\sigma` is the scalar.

Example::

   smooth_l1([1, 2, 3, 4]) = [0.5, 1.5, 2.5, 3.5]  
   smooth_l1([1, 2, 3, 4], scalar=1) = [0.5, 1.5, 2.5, 3.5]

Defined in src/operator/tensor/elemwise_binary_scalar_op_extended.cc:L109

Value

out The result mx.symbol

mx.symbol.Softmax

Softmax: Computes the gradient of cross entropy loss with respect to softmax output.

Description

- This operator computes the gradient in two steps. The cross entropy loss does not actually need to be computed.

Usage

.. code::

   mx.symbol.Softmax(...)
### Arguments

- **data**: NDArray-or-Symbol Input array.
- **label**: NDArray-or-Symbol Ground truth label.
- **grad.scale**: float, optional, default=1 Scales the gradient by a float factor.
- **ignore.label**: float, optional, default=-1 The instances whose 'labels' == 'ignore_label' will be ignored during backward, if 'use_ignore' is set to "true".
- **multi.output**: boolean, optional, default=0 If set to “true”, the softmax function will be computed along axis “1”. This is applied when the shape of input array differs from the shape of label array.
- **use.ignore**: boolean, optional, default=0 If set to “true”, the ‘ignore_label‘ value will not contribute to the backward gradient.
- **preserve.shape**: boolean, optional, default=0 If set to “true”, the softmax function will be computed along the last axis (“-1”).
- **normalization**: 'batch', 'null', 'valid', optional, default='null' Normalizes the gradient.
- **out.grad**: boolean, optional, default=0 Multiplies gradient with output gradient element-wise.
- **smooth.alpha**: float, optional, default=0 Constant for computing a label smoothed version of cross-entropy for the backwards pass. This constant gets subtracted from the one-hot encoding of the gold label and distributed uniformly to all other labels.
- **name**: string, optional Name of the resulting symbol.

### Details

- Applies softmax function on the input array. - Computes and returns the gradient of cross entropy loss w.r.t. the softmax output.
- The softmax function, cross entropy loss and gradient is given by:
- \[ \text{Softmax Function:} \]
\[
\text{softmax}(x)_i = \frac{\exp(x_i)}{\sum_j \exp(x_j)}
\]
- \[ \text{Cross Entropy Function:} \]
\[
\text{CE}(\text{label}, \text{output}) = - \sum_i \text{label}_i \log(\text{output}_i)
\]
- The gradient of cross entropy loss w.r.t softmax output:
\[
\text{gradient} = \text{output} - \text{label}
\]
- During forward propagation, the softmax function is computed for each instance in the input array. For general *N*-D input arrays with shape `(d_1, d_2, ..., d_n)`. The size is `s=d_1 \cdot d_2 \cdot \cdot \cdot d_n`. We can use the parameters 'preserve_shape' and 'multi_output' to specify the way to compute softmax:
- By default, ‘preserve_shape’ is “false”. This operator will reshape the input array into a 2-D array with shape `(d_1, \frac{s}{d_1})` and then compute the softmax function for each row in the reshaped array, and afterwards reshape it back to the original shape `(d_1, d_2, ..., d_n)`. If ‘preserve_shape’ is “true”, the softmax function will be computed along the last axis (‘axis’ = “-1”). If ‘multi_output’ is “true”, the softmax function will be computed along the second axis (‘axis’ = “1”).
- During backward propagation, the gradient of cross-entropy loss w.r.t softmax output array is computed. The provided label can be a one-hot label array or a probability label array.
- If the parameter `use_ignore` is "true", `ignore_label` can specify input instances with a particular label to be ignored during backward propagation. **This has no effect when softmax 'output' has same shape as 'label'**.

Example::

data = [[1,2,3,4],[2,2,2,2],[3,3,3,3],[4,4,4,4]] label = [1,0,2,3] ignore_label = 1
SoftmaxOutput(data=data, label = label, multi_output=true, use_ignore=true, ignore_label=ignore_label) ## forward softmax
output 
```
[ 0.0320586 0.08714432 0.23688284 0.64391428 ]
[ 0.25 0.25 0.25 0.25 ]
[ 0.25 0.25 0.25 0.25 ]
[ 0.25 0.25 0.25 0.25 ]
```
## backward gradient output 
```
[ 0. 0. 0. 0.]
[-0.75 0.25 0.25 0.25]
[ 0.25 0.25 -0.75 0.25]
[ 0.25 0.25 0.25 -0.75]
```
## notice that the first row is all 0 because label[0] is 1, which is equal to ignore_label.

- The parameter `grad_scale` can be used to rescale the gradient, which is often used to give each loss function different weights.
- This operator also supports various ways to normalize the gradient by `normalization`. The `normalization` is applied if softmax output has different shape than the labels. The `normalization` mode can be set to the followings:
  - "'null'": do nothing. - "'batch'": divide the gradient by the batch size. - "'valid'": divide the gradient by the number of instances which are not ignored.

Defined in src/operator/softmax_output.cc:L243

Value

out The result mx.symbol

mx.symbol.softmax

softmax: Applies the softmax function.

Description

The resulting array contains elements in the range (0,1) and the elements along the given axis sum up to 1.

Usage

mx.symbol.softmax(...) 

Arguments

data NDArray-or-Symbol The input array.
length NDArray-or-Symbol The length array.
axis int, optional, default='-1' The axis along which to compute softmax.
temperature double or None, optional, default=None Temperature parameter in softmax
mx.symbol.SoftmaxActivation

dtype  None, 'float16', 'float32', 'float64', optional, default='None' DType of the output in case this can’t be inferred. Defaults to the same as input’s dtype if not defined (dtype=None).

use.length  boolean or None, optional, default=0 Whether to use the length input as a mask over the data input.

name  string, optional Name of the resulting symbol.

Details

.. math:: softmax\left(\frac{\mathbf{z}}{t}\right)_j = \frac{e^{z_j}}{\sum_{k=1}^{K} e^{z_k}}/t

for \: j = 1, \ldots, K\:

t is the temperature parameter in softmax function. By default, t equals 1.0

Example:

\begin{verbatim}
x = [[[ 1.  1.  1.]]
     [[ 1.  1.  1.]]]
softmax(x,axis=0) = [[[ 0.5 0.5 0.5]]
                     [[ 0.5 0.5 0.5]]]
softmax(x,axis=1) = [[[ 0.33333334, 0.33333334, 0.33333334],
                               [ 0.33333334, 0.33333334, 0.33333334]]
                     [[[ 0.33333334, 0.33333334, 0.33333334],
                               [ 0.33333334, 0.33333334, 0.33333334]]]}
\end{verbatim}

Defined in src/operator/nn/softmax.cc:L136

Value

out The result mx.symbol

mx.symbol.SoftmaxActivation

SoftmaxActivation: Applies softmax activation to input. This is intended for internal layers.

Description

.. note::

Usage

mx.symbol.SoftmaxActivation(...)

Arguments

data  NDArray-or-Symbol The input array.

mode  'channel', 'instance', optional, default='instance' Specifies how to compute the softmax. If set to "instance", it computes softmax for each instance. If set to "channel", it computes cross channel softmax for each position of each instance.

name  string, optional Name of the resulting symbol.
mx.symbol.SoftmaxOutput

Details

This operator has been deprecated, please use ‘softmax’.

If ‘mode’ = “instance”, this operator will compute a softmax for each instance in the batch. This is the default mode.

If ‘mode’ = “channel”, this operator will compute a k-class softmax at each position of each instance, where ‘k’ = “num_channel”. This mode can only be used when the input array has at least 3 dimensions. This can be used for ‘fully convolutional network’, ‘image segmentation’, etc.

Example::

```python
>>> input_array = mx.nd.array([[3., 0.5, -0.5, 2., 7.],
                         [2., -4., 7., 3., 0.2]])
>>> softmax_act = mx.nd.SoftmaxActivation(input_array)
>>> print softmax_act.asnumpy()
[[ 1.78322066e-02 1.46375655e-03 5.38485940e-04 6.56010211e-03 9.73605454e-01]
 [ 6.56221947e-03 5.95310994e-04 9.73919690e-01 1.78379621e-02 1.08472735e-03]]
```

Defined in src/operator/nn/softmax_activation.cc:L59

Value

out The result mx.symbol

mx.symbol.SoftmaxOutput

**SoftmaxOutput:** Computes the gradient of cross entropy loss with respect to softmax output.

Description

- This operator computes the gradient in two steps. The cross entropy loss does not actually need to be computed.

Usage

mx.symbol.SoftmaxOutput(...)

Arguments

data NDArray-or-Symbol Input array.

label NDArray-or-Symbol Ground truth label.

grad.scale float, optional, default=1 Scales the gradient by a float factor.

ignore.label float, optional, default=-1 The instances whose ‘labels’ == ‘ignore_label’ will be ignored during backward, if ‘use_ignore’ is set to “true”).

multi.output boolean, optional, default=0 If set to “true", the softmax function will be computed along axis “1”. This is applied when the shape of input array differs from the shape of label array.

use.ignore boolean, optional, default=0 If set to “true”, the ‘ignore_label’ value will not contribute to the backward gradient.
mx.symbol.SoftmaxOutput

- Applies softmax function on the input array. - Computes and returns the gradient of cross entropy loss w.r.t. the softmax output.
- The softmax function, cross entropy loss and gradient is given by:
  - Softmax Function:
    \[
    \text{softmax}(x)_i = \frac{\exp(x_i)}{\sum_j \exp(x_j)}
    \]
  - Cross Entropy Function:
    \[
    \text{CE}(\text{label}, \text{output}) = - \sum_i \text{label}_i \log(\text{output}_i)
    \]
  - The gradient of cross entropy loss w.r.t softmax output:
    \[
    \text{gradient} = \text{output} - \text{label}
    \]
- During forward propagation, the softmax function is computed for each instance in the input array. For general \(N\)-D input arrays with shape \(d_1, d_2, \ldots, d_n\). The size is \(s = d_1 \cdot d_2 \cdot \ldots \cdot d_n\). We can use the parameters 'preserve_shape' and 'multi_output' to specify the way to compute softmax:
  - By default, 'preserve_shape' is "false". This operator will reshape the input array into a 2-D array with shape \(d_1, \frac{sd_1}{d_1} \cdot d_2 \cdot \ldots \cdot d_n\). Then compute the softmax function for each row in the reshaped array, and afterwards reshape it back to the original shape \(d_1, d_2, \ldots, d_n\).
  - If 'preserve_shape' is "true", the softmax function will be computed along the last axis ('axis' = "-1"). If 'multi_output' is "true", the softmax function will be computed along the second axis ('axis' = "1").

Defined in src/operator/softmax_output.cc:L243

Value

out The result mx.symbol

mx.symbol.softmax_cross_entropy
softmax_cross_entropy: Calculate cross entropy of softmax output and one-hot label.

Description

- This operator computes the cross entropy in two steps: - Applies softmax function on the input array. - Computes and returns the cross entropy loss between the softmax output and the labels.

Usage

mx.symbol.softmax_cross_entropy(...)

Arguments

data NDArray-or-Symbol Input data
label NDArray-or-Symbol Input label
name string, optional Name of the resulting symbol.

Details

- The softmax function and cross entropy loss is given by:
  - Softmax Function:
    .. math:: \text{softmax}(x)_i = \frac{\exp(x_i)}{\sum_j \exp(x_j)}
  - Cross Entropy Function:
    .. math:: \text{CE}(label, output) = - \sum_i \text{label}_i \log(\text{output}_i)
Example::
x = [[1, 2, 3], [11, 7, 5]]
label = [2, 0]
softmax(x) = [[0.09003057, 0.24472848, 0.66524094], [0.97962922, 0.01794253, 0.00242826]]
softmax_cross_entropy(data, label) = - log(0.66524084) - log(0.97962922) = 0.4281871
Defined in src/operator/loss_binary_op.cc:L59
Value

out The result mx.symbol

mx.symbol.softmin    softmin: Applies the softmin function.

Description

The resulting array contains elements in the range (0,1) and the elements along the given axis sum up to 1.

Usage

mx.symbol.softmin(...)

Arguments

data NDArray-or-Symbol The input array.
axis int, optional, default='-1' The axis along which to compute softmax.
temperature double or None, optional, default=None Temperature parameter in softmax
dtype None, 'float16', 'float32', 'float64', optional, default=None DType of the output in case this can’t be inferred. Defaults to the same as input’s dtype if not defined (dtype=None).
use.length boolean or None, optional, default=0 Whether to use the length input as a mask over the data input.
name string, optional Name of the resulting symbol.

Details

.. math:: \text{softmin}(\mathbf{z}/t)_j = \frac{e^{-z_j}}{\sum_k=1^K e^{-z_k}/t}

for :math:`j = 1, ..., K`

t is the temperature parameter in softmax function. By default, t equals 1.0

Example::

x = [[ 1.  2.  3.],[ 3.  2.  1.]]
softmin(x, axis=0) = [[ 0.88079703, 0.511920292, 0.11920292], [ 0.11920292, 0.511920292, 0.88079703]]
softmin(x, axis=1) = [[ 0.66524094, 0.24472848, 0.09003057], [ 0.09003057, 0.24472848, 0.66524094]]

Defined in src/operator/nn/softmin.cc:L57

Value

out The result mx.symbol
mx.symbol.softsign  

**softsign:** Computes softsign of x element-wise.

Description

.. math:: y = x / (1 + \text{abs}(x))

Usage

mx.symbol.softsign(...)  

Arguments

data  NDArray-or-Symbol  The input array.
name  string, optional  Name of the resulting symbol.

Details

The storage type of "softsign" output is always dense.

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L191

Value

out  The result mx.symbol

mx.symbol.sort  

**sort:** Returns a sorted copy of an input array along the given axis.

Description

Examples::

Usage

mx.symbol.sort(...)  

Arguments

data  NDArray-or-Symbol  The input array
axis  int or None, optional, default='1'  Axis along which to choose sort the input tensor. If not given, the flattened array is used. Default is -1.
is.ascend  boolean, optional, default=1  Whether to sort in ascending or descending order.
name  string, optional  Name of the resulting symbol.
Details

\[ x = \begin{bmatrix} 1 & 4 \\ 3 & 1 \end{bmatrix} \]

// sorts along the last axis 
\[ \text{sort}(x) = \begin{bmatrix} 1. & 4. \\ 1. & 3. \end{bmatrix} \]

// flattens and then sorts 
\[ \text{sort}(x, \text{axis=None}) = [1., 1., 3., 4.] \]

// sorts along the first axis 
\[ \text{sort}(x, \text{axis=0}) = \begin{bmatrix} 1. & 1. \\ 3. & 4. \end{bmatrix} \]

// in a descend order 
\[ \text{sort}(x, \text{is_ascend=0}) = \begin{bmatrix} 4. & 1. \\ 3. & 1. \end{bmatrix} \]

Defined in src/operator/tensor/ordering_op.cc:L133

Value

\[
\text{out} \quad \text{The result mx.symbol}\\
\]

mx.symbol.space_to_depth

\[ \text{space_to_depth}: \text{Rearranges(permutes) blocks of spatial data into depth. Similar to ONNX SpaceToDepth operator: https://github.com/onnx/onnx/blob/master/docs/Operators.md#SpaceToDepth} \]

The output is a new tensor where the values from height and width dimension are moved to the depth dimension. The reverse of this operation is \"depth_to_space\". 

Math:: \[ x' = \text{reshape}(x, [N, C, H / \text{block_size}, \text{block_size}, W / \text{block_size}, \text{block_size}]) \]
\[ x'' = \text{transpose}(x', [0, 3, 5, 1, 2, 4]) \]
\[ y = \text{reshape}(x'', [N, C \times (\text{block_size}^2), H / \text{block_size}, W / \text{block_size}]) \]

where \[ x \] is an input tensor with default layout as \[ [N, C, H, W] \]: [batch, channels, height, width] and \[ y \] is the output tensor of layout \[ [N, C \times (\text{block_size}^2), H / \text{block_size}, W / \text{block_size}] \].

Example::

\[
\begin{bmatrix} 0 & 6 & 1 & 7 & 2 & 8 \\ 12 & 18 & 13 & 19 & 14 & 20 \\ 3 & 9 & 4 & 10 & 5 & 11 \\ 15 & 21 & 16 & 22 & 17 & 23 \end{bmatrix}
\]

\[
\text{space_to_depth}(x, 2) = \begin{bmatrix} 0 & 1 & 2 \\ 6 & 7 & 8 \\ 12 & 13 & 14 \\ 18 & 19 & 20 \\ 21 & 22 & 23 \end{bmatrix}
\]

Description

Defined in src/operator/tensor/matrix_op.cc:L1019

Usage

mx.symbol.space_to_depth(…)

Arguments

- **data**: NDArray-or-Symbol Input ndarray
- **block.size**: int, required Blocks of [block.size, block.size] are moved
- **name**: string, optional Name of the resulting symbol.
**mx.symbol.SpatialTransformer**

*SpatialTransformer*: Applies a spatial transformer to input feature map.

**Description**

SpatialTransformer: Applies a spatial transformer to input feature map.

**Usage**

```python
mx.symbol.SpatialTransformer(...)
```

**Arguments**

- **data**: NDArray-or-Symbol Input data to the SpatialTransformerOp.
- **loc**: NDArray-or-Symbol localisation net, the output dim should be 6 when transform_type is affine. You should initialize the weight and bias with identity transform.
- **target.shape**: Shape(tuple), optional, default=[0,0] output shape(h, w) of spatial transformer: (y, x)
- **transform.type**: 'affine', required transformation type
- **sampler.type**: 'bilinear', required sampling type
- **cudnn.off**: boolean or None, optional, default=None whether to turn cudnn off
- **name**: string, optional Name of the resulting symbol.

**Value**

```python
out The result mx.symbol
```
**mx.symbol.split**  

**split:** Splits an array along a particular axis into multiple sub-arrays.

### Description

.. note:: “SliceChannel” is deprecated. Use “split” instead.

### Usage

```python
mx.symbol.split(...)
```

### Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>data</code></td>
<td>NDArray-or-Symbol The input</td>
</tr>
<tr>
<td><code>num.outputs</code></td>
<td>int, required Number of splits. Note that this should evenly divide the length of the 'axis'.</td>
</tr>
<tr>
<td><code>axis</code></td>
<td>int, optional, default='1' Axis along which to split.</td>
</tr>
<tr>
<td><code>squeeze.axis</code></td>
<td>boolean, optional, default=0 If true, Removes the axis with length 1 from the shapes of the output arrays. <strong>Note</strong> that setting 'squeeze_axis' to “true” removes axis with length 1 only along the ‘axis’ which it is split. Also ‘squeeze_axis’ can be set to “true” only if “input.shape[axis] == num_outputs”.</td>
</tr>
<tr>
<td><code>name</code></td>
<td>string, optional Name of the resulting symbol</td>
</tr>
</tbody>
</table>

### Details

**Note** that `num_outputs` should evenly divide the length of the axis along which to split the array.

Example::

```python
x = [[[ 1. ] [ 2. ]] [[ 3. ] [ 4. ]] [[ 5. ] [ 6. ]]] x.shape = (3, 2, 1)
y = split(x, axis=1, num_outputs=2) // a list of 2 arrays with shape (3, 1, 1) y = [[[ 1. ] [ 3. ] [ 5. ]]
[[[ 2. ] [ 4. ] [ 6. ]]] y[0].shape = (3, 1, 1)
z = split(x, axis=0, num_outputs=3) // a list of 3 arrays with shape (1, 2, 1) z = [[[ 1. ] [ 2. ]]]
[[[ 3. ] [ 4. ]] [[ 5. ] [ 6. ]]] z[0].shape = (1, 2, 1)
```

‘squeeze_axis=1’ removes the axis with length 1 from the shapes of the output arrays. **Note** that setting ‘squeeze_axis’ to “1” removes axis with length 1 only along the ‘axis’ which it is split. Also ‘squeeze_axis’ can be set to true only if “input.shape[axis] == num_outputs”.

Example::

```python
z = split(x, axis=0, num_outputs=3, squeeze_axis=1) // a list of 3 arrays with shape (2, 1) z = [[ 1. ] [ 2. ]]
```
mx.symbol.sqrt

```
[[ 3.] [ 4.]]
[[ 5.] [ 6.]] z[0].shape = (2, 1 )
Defined in src/operator/slice_channel.cc:L107
```

Value

```
out The result mx.symbol
```

mx.symbol.sqrt  

```
sqrt:Returns element-wise square-root value of the input.
```

Description

```
.. math:: \textrm{sqrt}(x) = \sqrt{x}
```

Usage

```
mx.symbol.sqrt(...)
```

Arguments

```
data NDArray-or-Symbol The input array.
name string, optional Name of the resulting symbol.
```

Details

Example::

```
sqrt([4, 9, 16]) = [2, 3, 4]
```

The storage type of “sqrt” output depends upon the input storage type:

```
- sqrt(default) = default - sqrt(row_sparse) = row_sparse - sqrt(csr) = csr
```

Defined in src/operator/tensor/elemwise_unary_op_pow.cc:L170

Value

```
out The result mx.symbol
```
square: Returns element-wise squared value of the input.

Description

.. math:: square(x) = x^2

Usage

mx.symbol.square(...)

Arguments

data: NDArray-or-Symbol The input array.
name: string, optional Name of the resulting symbol.

Details

Example:

square([2, 3, 4]) = [4, 9, 16]

The storage type of “square” output depends upon the input storage type:
- square(default) = default
- square(row_sparse) = row_sparse
- square(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_pow.cc:L119

Value

out The result mx.symbol

squeeze: Remove single-dimensional entries from the shape of an array. Same behavior of defining the output tensor shape as numpy.squeeze for the most of cases. See the following note for exception. Examples:

data = [[[0], [1], [2]]]

squeeze(data) = [0, 1, 2]
squeeze(data, axis=0) = [[0], [1], [2]]
squeeze(data, axis=2) = [[0, 1, 2]]
squeeze(data, axis=(0, 2)) = [0, 1, 2] .. Note: The output of this operator will keep at least one dimension not removed. For example, squeeze([[4]]) = [4], while in numpy.squeeze, the output will become a scalar.
Description

squeeze: Remove single-dimensional entries from the shape of an array. Same behavior of defining the output tensor shape as numpy.squeeze for the most of cases. See the following note for exception. Examples:

```python
import numpy as np
data = np.array([[[0], [1], [2]]])
squeeze(data) = [0, 1, 2]
squeeze(data, axis=0) = [[0], [1], [2]]
squeeze(data, axis=2) = [[0, 1, 2]]
squeeze(data, axis=(0, 2)) = [0, 1, 2].. Note: The output of this operator will keep at least one dimension not removed. For example, squeeze([[[4]]]) = [4], while in numpy.squeeze, the output will become a scalar.
```

Usage

```
mx.symbol.squeeze(...)
```

Arguments

- **data**: NDArray-or-Symbol data to squeeze
- **axis**: Shape or None, optional, default=None Selects a subset of the single-dimensional entries in the shape. If an axis is selected with shape entry greater than one, an error is raised.
- **name**: string, optional Name of the resulting symbol.

Value

```
out The result mx.symbol
```

Description

stack: Join a sequence of arrays along a new axis. The axis parameter specifies the index of the new axis in the dimensions of the result. For example, if axis=0 it will be the first dimension and if axis=-1 it will be the last dimension. Examples:

```python
x = [1, 2] y = [3, 4] stack(x, y) = [[1, 2], [3, 4]]
stack(x, y, axis=1) = [[1, 3], [2, 4]]
```

Usage

```
mx.symbol.stack(...)
```
mx.symbol.stop_gradient

**Arguments**

- **data**: NDArray-or-Symbol[] List of arrays to stack
- **axis**: int, optional, default='0' The axis in the result array along which the input arrays are stacked.
- **num_args**: int, required Number of inputs to be stacked.
- **name**: string, optional Name of the resulting symbol.

**Value**

- **out**: The result mx.symbol

---

**Description**

Stops the accumulated gradient of the inputs from flowing through this operator in the backward direction. In other words, this operator prevents the contribution of its inputs to be taken into account for computing gradients.

**Usage**

```
mx.symbol.stop_gradient(...)
```

**Arguments**

- **data**: NDArray-or-Symbol The input array.
- **name**: string, optional Name of the resulting symbol.

**Details**

Example:
```
v1 = [1, 2] v2 = [0, 1] a = Variable('a') b = Variable('b') b_stop_grad = stop_gradient(3 * b) loss = MakeLoss(b_stop_grad + a)
executor = loss.simple_bind(ctx=cpu(), a=(1,2), b=(1,2)) executor.forward(is_train=True, a=v1, b=v2)
executor.backward() executor.grad_arrays [ 0. 0. ] [ 1. 1.]
```

Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L325

**Value**

- **out**: The result mx.symbol
mx.symbol.sum

**Description**

.. Note::

**Usage**

mx.symbol.sum(...)

**Arguments**

- **data**: NDArray-or-Symbol The input
- **axis**: Shape or None, optional, default=None The axis or axes along which to perform the reduction.
  The default, ‘axis=()’, will compute over all elements into a scalar array with shape ‘(1,)’.
  If ‘axis’ is int, a reduction is performed on a particular axis.
  If ‘axis’ is a tuple of ints, a reduction is performed on all the axes specified in the tuple.
  If ‘exclude’ is true, reduction will be performed on the axes that are NOT in axis instead.
  Negative values means indexing from right to left.
- **keepdims**: boolean, optional, default=0 If this is set to ‘True’, the reduced axes are left in the result as dimension with size one.
- **exclude**: boolean, optional, default=0 Whether to perform reduction on axis that are NOT in axis instead.
- **name**: string, optional Name of the resulting symbol.

**Details**

‘sum’ and ‘sum_axis’ are equivalent. For ndarray of csr storage type summation along axis 0 and axis 1 is supported. Setting keepdims or exclude to True will cause a fallback to dense operator.

Example::

data = [[[1, 2], [2, 3], [1, 3]], [[1, 4], [4, 3], [5, 2]], [[7, 1], [7, 2], [7, 3]]
sum(data, axis=1) [[ 4.  8. ] [10.  9. ] [21.  6.]]
sum(data, axis=1, [ ] [ 12. 19. 27.]
data = [[1, 2, 0], [3, 0, 1], [4, 1, 0]]
csr = cast_storage(data, 'csr')
sum(csr, axis=0) [ 8.  3.  1.]
sum(csr, axis=1) [ 3.  4.  5.]

Defined in src/operator/tensor/broadcast_reduce_sum_value.cc:L67
mx.symbol.sum_axis

**Value**

out The result mx.symbol

---

mx.symbol.sum_axis

**sum_axis:** Computes the sum of array elements over given axes.

---

**Description**

.. Note::

**Usage**

mx.symbol.sum_axis(...)

**Arguments**

- **data**
  - NDArray-or-Symbol: The input
- **axis**
  - Shape or None, optional, default=None: The axis or axes along which to perform the reduction.
  
  The default, ‘axis=()’, will compute over all elements into a scalar array with shape ‘(1,)’.
  
  If ‘axis’ is int, a reduction is performed on a particular axis.
  
  If ‘axis’ is a tuple of ints, a reduction is performed on all the axes specified in the tuple.
  
  If ‘exclude’ is true, reduction will be performed on the axes that are NOT in axis instead.
  
  Negative values means indexing from right to left.

- **keepdims**
  - boolean, optional, default=0: If this is set to ‘True’, the reduced axes are left in the result as dimension with size one.

- **exclude**
  - boolean, optional, default=0: Whether to perform reduction on axis that are NOT in axis instead.

- **name**
  - string, optional: Name of the resulting symbol.

**Details**

‘sum’ and ‘sum_axis’ are equivalent. For ndarray of csr storage type summation along axis 0 and axis 1 is supported. Setting keepdims or exclude to True will cause a fallback to dense operator.

Example::

data = [[[1, 2], [2, 3], [1, 3]], [[1, 4], [4, 3], [5, 2]], [[7, 1], [7, 2], [7, 3]]]

sum(data, axis=1) [[ 4.  8. ] [ 10. 9. ] [21. 6.]]

sum(data, axis=1) [[ 4.  8. ] [ 10. 9. ] [21. 6.]]

data = [[1, 2, 0], [3, 0, 1], [4, 1, 0]]
csr = cast_storage(data, ‘csr’)
**mx.symbol.SVMOutput**

sum(csr, axis=0) [ 8. 3. 1.]
sum(csr, axis=1) [ 3. 4. 5.]

Defined in src/operator/tensor/broadcast_reduce_sum_value.cc:L67

**Value**

out The result mx.symbol

**Description**

This tutorial demonstrates using SVM as output layer for classification instead of softmax: https://github.com/dmlc/mxnet/tree/master/example/svm_mnist.

**Usage**

mx.symbol.SVMOutput(...)

**Arguments**

- **data** NDArray-or-Symbol Input data for SVM transformation.
- **label** NDArray-or-Symbol Class label for the input data.
- **margin** float, optional, default=1 The loss function penalizes outputs that lie outside this margin. Default margin is 1.
- **regularization.coefficient** float, optional, default=1 Regularization parameter for the SVM. This balances the tradeoff between coefficient size and error.
- **use.linear** boolean, optional, default=0 Whether to use L1-SVM objective. L2-SVM objective is used by default.
- **name** string, optional Name of the resulting symbol.

**Value**

out The result mx.symbol
mx.symbol.swapaxes

*swapaxes: Interchanges two axes of an array.*

**Description**

Examples::

**Usage**

mx.symbol.swapaxes(...)

**Arguments**

data NDArray-or-Symbol Input array.
dim1 int, optional, default='0' the first axis to be swapped.
dim2 int, optional, default='0' the second axis to be swapped.
name string, optional Name of the resulting symbol.

**Details**

\[ x = \begin{bmatrix} 1, 2, 3 \end{bmatrix} \] swapaxes(x, 0, 1) = \begin{bmatrix} 1, 2, 3 \end{bmatrix}

\[ x = \begin{bmatrix} 0, 1, 2, 3 \end{bmatrix} \] // (2,2,2) array

swapaxes(x, 0, 2) = \begin{bmatrix} 0, 4, 1, 5 \end{bmatrix} \begin{bmatrix} 2, 6, 3, 7 \end{bmatrix}

Defined in src/operator/swapaxis.cc:L70

**Value**

out The result mx.symbol

mx.symbol.SwapAxis

*SwapAxis: Interchanges two axes of an array.*

**Description**

Examples::

**Usage**

mx.symbol.SwapAxis(...)
Arguments

data  NDArray-or-Symbol Input array.
dim1  int, optional, default='0' the first axis to be swapped.
dim2  int, optional, default='0' the second axis to be swapped.
name  string, optional Name of the resulting symbol.

Details

x = [[1, 2, 3]]) swapaxes(x, 0, 1) = [[1], [2], [3]]
x = [[[0, 1], [2, 3]], [[4, 5], [6, 7]]] // (2,2,2) array
swapaxes(x, 0, 2) = [[[0, 4], [2, 6]], [[1, 5], [3, 7]]]
Defined in src/operator/swapaxis.cc:L70

Value

out The result mx.symbol

Description

This function slices the input array along a particular axis with the provided indices.

Usage

mx.symbol.take(...)
Details

Given data tensor of rank \( r \geq 1 \), and indices tensor of rank \( q \), gather entries of the axis dimension of data (by default outer-most one as axis=0) indexed by indices, and concatenates them in an output tensor of rank \( q + (r - 1) \).

Examples:

\[
x = [4.\; 5.\; 6.]
\]

// Trivial case, take the second element along the first axis.

\[
take(x, \{1\}) = [5.]
\]

// The other trivial case, axis=-1, take the third element along the first axis

\[
take(x, \{3\}, axis=-1, mode='clip') = [6.]
\]

\[
x = [[1.\; 2.], [3.\; 4.], [5.\; 6.]]
\]

// In this case we will get rows 0 and 1, then 1 and 2. Along axis 0

\[
take(x, [[0,1],[1,2]]) = [[[1.\; 2.], [3.\; 4.]],
[[3.\; 4.], [5.\; 6.]]]
\]

// In this case we will get rows 0 and 1, then 1 and 2 (calculated by wrapping around). // Along axis 1

\[
take(x, [[0, 3], [-1, -2]], axis=1, mode='wrap') = [[[1.\; 2.], [2.\; 1.]],
[[3.\; 4.], [4.\; 3.]],
[[5.\; 6.], [6.\; 5.]]]
\]

The storage type of “take” output depends upon the input storage type:

- take(default, default) = default - take(csr, default, axis=0) = csr

Defined in src/operator/tensor/indexing_op.cc:L777

Value

out The result mx.symbol

mx.symbol.tan

\text{tan}: \text{Computes the element-wise tangent of the input array.}

Description

The input should be in radians (\(2\pi\) rad equals 360 degrees).

Usage

mx.symbol.tan(…)

Arguments

data NDArray-or-Symbol The input array.

name string, optional Name of the resulting symbol.
mx.symbol.tanh

Details

.. math:: \tan([0, \pi/4, \pi/2]) = [0, 1, -\infty]

The storage type of “tan” output depends upon the input storage type:
- tan(default) = default - tan(row_sparse) = row_sparse - tan(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L140

Value

out The result mx.symbol

mx.symbol.tanh

.. math:: \tanh(x) = \sinh(x) / \cosh(x)

tanh:Returns the hyperbolic tangent of the input array, computed element-wise.

Usage

mx.symbol.tanh(...)

Arguments

data NDArray-or-Symbol The input array.

name string, optional Name of the resulting symbol.

Details

The storage type of “tanh” output depends upon the input storage type:
- tanh(default) = default - tanh(row_sparse) = row_sparse - tanh(csr) = csr

Defined in src/operator/tensor/elemwise_unary_op_trig.cc:L451

Value

out The result mx.symbol
mx.symbol.tile

*tile*: Repeats the whole array multiple times. If “reps“ has length *d*, and input array has dimension of *n*. There are three cases:

- **n=d**. Repeat *i*-th dimension of the input by “reps[i]“ times::

  \[x = \begin{bmatrix} [1, 2], [3, 4] \end{bmatrix}\]

  \[\text{tile}(x, \text{reps}=(2,3)) = \begin{bmatrix} [1, 2, 1, 2, 1, 2], [3, 4, 3, 4, 3, 4], [1, 2, 1, 2, 1, 2], [3, 4, 3, 4, 3, 4] \end{bmatrix}\] - **n>d**

“reps“ is promoted to length *n* by pre-pending 1’s to it. Thus for an input shape “(2,3)“, “repos=(2,)“ is treated as “(1,2)“::

\[\text{tile}(x, \text{reps}=(2,)) = \begin{bmatrix} [1, 2, 1, 2], [3, 4, 3, 4] \end{bmatrix}\] - **n<d**

The input is promoted to be d-dimensional by prepending new axes. So a shape “(2,2)“ array is promoted to “(1,2,2)” for 3-D replication::

\[\text{tile}(x, \text{reps}=(2,2,3)) = \begin{bmatrix} [1, 2, 1, 2, 1, 2], [3, 4, 3, 4, 3, 4], [1, 2, 1, 2, 1, 2], [3, 4, 3, 4, 3, 4], [1, 2, 1, 2, 1, 2], [3, 4, 3, 4, 3, 4] \end{bmatrix}\]

Description

Defined in src/operator/tensor/matrix_op.cc:L796

Usage

mx.symbol.tile(...)

Arguments

data NDArray-or-Symbol Input data array

reps Shape(tuple), required The number of times for repeating the tensor a. Each dim size of reps must be a positive integer. If reps has length d, the result will have dimension of max(d, a.ndim); If a.ndim < d, a is promoted to be d-dimensional by prepending new axes. If a.ndim > d, reps is promoted to a.ndim by pre-pending 1’s to it.

name string, optional Name of the resulting symbol.

Value

out The result mx.symbol

mx.symbol.topk

topk: Returns the indices of the top *k* elements in an input array along the given axis (by default). If ret_type is set to ‘value‘ returns the value of top *k* elements (instead of indices). In case of ret_type = ‘both‘, both value and index would be returned. The returned elements will be sorted.
Description

Examples::

Usage

mx.symbol.topk(...)

Arguments

data NDArray-or-Symbol The input array
axis int or None, optional, default='-1' Axis along which to choose the top k indices. If not given, the flattened array is used. Default is -1.
k int, optional, default='1' Number of top elements to select, should be always smaller than or equal to the element number in the given axis. A global sort is performed if set k < 1.
ret.typ 'both', 'indices', 'mask', 'value'.optional, default='indices' The return type. "value" means to return the top k values, "indices" means to return the indices of the top k values, "mask" means to return a mask array containing 0 and 1. 1 means the top k values. "both" means to return a list of both values and indices of top k elements.
is.ascend boolean, optional, default=0 Whether to choose k largest or k smallest elements. Top K largest elements will be chosen if set to false.
dtype 'float16', 'float32', 'float64', 'int32', 'int64', 'uint8'.optional, default='float32' Dtype of the output indices when ret_typ is "indices" or "both". An error will be raised if the selected data type cannot precisely represent the indices.
name string, optional Name of the resulting symbol.

Details

x = [[ 0.3, 0.2, 0.4], [ 0.1, 0.3, 0.2]]
// returns an index of the largest element on last axis topk(x) = [[ 2.], [ 1.]]
// returns the value of top-2 largest elements on last axis topk(x, ret_typ='value', k=2) = [[ 0.4, 0.3], [ 0.3, 0.2]]
// returns the value of top-2 smallest elements on last axis topk(x, ret_typ='value', k=2, is_ascend=1) = [[ 0.2, 0.3], [ 0.1, 0.2]]
// returns the value of top-2 largest elements on axis 0 topk(x, axis=0, ret_typ='value', k=2) = [[ 0.3, 0.3, 0.4], [ 0.1, 0.2, 0.2]]
// flattens and then returns list of both values and indices topk(x, ret_typ='both', k=2) = [[[ 0.4, 0.3], [ 0.3, 0.2]], [[ 2., 0.], [ 1., 2.]]]
Defined in src/operator/tensor/ordering_op.cc:L68

Value

out The result mx.symbol
mx.symbol.transpose

**transpose:** Permutations the dimensions of an array. Examples:

\[ x = \begin{bmatrix} 1, 2, 3, 4 \end{bmatrix} \]

\[ \text{transpose}(x) = \begin{bmatrix} 1, 3, 2, 4 \end{bmatrix} \]

\[ x = \begin{bmatrix} 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 \end{bmatrix} \]

\[ \text{transpose}(x) = \begin{bmatrix} 1, 5, 9, 3, 7, 11, 2, 6, 10, 4 \end{bmatrix} \]

\[ x = \begin{bmatrix} 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 \end{bmatrix} \]

\[ \text{transpose}(x, \text{axes}=(3, 1)) = \begin{bmatrix} 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 \end{bmatrix} \]

---

**Description**

Defined in src/operator/tensor/matrix_op.cc:L328

**Usage**

\[
\text{mx.symbol.transpose}(\ldots)
\]

**Arguments**

- **data**: NDArray-or-Symbol Source input
- **axes**: Shape(tuple), optional, default=[] Target axis order. By default the axes will be inverted.
- **name**: string, optional Name of the resulting symbol.

**Value**

out The result mx.symbol

mx.symbol.trunc

**trunc:** Return the element-wise truncated value of the input.

---

**Description**

The truncated value of the scalar x is the nearest integer i which is closer to zero than x is. In short, the fractional part of the signed number x is discarded.

**Usage**

\[
\text{mx.symbol.trunc}(\ldots)
\]

**Arguments**

- **data**: NDArray-or-Symbol The input array.
- **name**: string, optional Name of the resulting symbol.
mx.symbol.uniform

Details

Example::
trunc([-2.1, -1.9, 1.5, 1.9, 2.1]) = [-2., -1., 1., 1., 2.]
The storage type of “trunc” output depends upon the input storage type:
- trunc(default) = default - trunc(row_sparse) = row_sparse - trunc(csr) = csr
Defined in src/operator/tensor/elemwise_unary_op_basic.cc:L856

Value

out The result mx.symbol

mx.symbol.uniform uniform:Draw random samples from a uniform distribution.

Description

.. note:: The existing alias “uniform” is deprecated.

Usage

mx.symbol.uniform(...)  

Arguments

low float, optional, default=0 Lower bound of the distribution.
high float, optional, default=1 Upper bound of the distribution.
shape Shape(tuple), optional, default=None Shape of the output.
ctx string, optional, default=” Context of output, in format [cpu|gpu|cpu_pinned](n). Only used for imperative calls.
dtype 'None', 'float16', 'float32', 'float64', optional, default='None' DType of the output in case this can’t be inferred. Defaults to float32 if not defined (dtype=None).
name string, optional Name of the resulting symbol.

Details

Samples are uniformly distributed over the half-open interval *[low, high)* (includes *low*, but excludes *high*).
Example::
uniform(low=0, high=1, shape=(2,2)) = [[ 0.60276335, 0.85794562], [ 0.54488319, 0.84725171]]
Defined in src/operator/random/sample_op.cc:L96

Value

out The result mx.symbol
mx.symbol.unravel_index

unravel_index: Converts an array of flat indices into a batch of index arrays. The operator follows numpy conventions so a single multi-index is given by a column of the output matrix. The leading dimension may be left unspecified by using -1 as placeholder.

Description

Examples:

Usage

mx.symbol.unravel_index(...)

Arguments

data NDArray-or-Symbol Array of flat indices
shape Shape(tuple), optional, default=None Shape of the array into which the multi-indices apply.
nname string, optional Name of the resulting symbol.

Details

A = [22, 41, 37] unravel(A, shape=(7, 6)) = [[3, 6, 6], [4, 5, 1]] unravel(A, shape=(-1, 6)) = [[3, 6, 6], [4, 5, 1]] Defined in src/operator/tensor/ravel.cc:L68

Value

out The result mx.symbol

mx.symbol.UpSampling

UpSampling: Upsamples the given input data.

Description

Two algorithms ("sample_type") are available for upsampling:

Usage

mx.symbol.UpSampling(...)

**mx.symbol.UpSampling**

### Arguments

- **data**: NDArray-or-Symbol[] Array of tensors to upsample. For bilinear upsampling, there should be 2 inputs - 1 data and 1 weight.
- **scale**: int, required Up sampling scale
- **num.filter**: int, optional, default='0' Input filter. Only used by bilinear sample_type. Since bilinear upsampling uses deconvolution, num_filters is set to the number of channels.
- **sample.type**: 'bilinear', 'nearest', required upsampling method
- **multi.input.mode**: 'concat', 'sum', optional, default='concat' How to handle multiple input. concat means concatenate upsampled images along the channel dimension. sum means add all images together, only available for nearest neighbor upsampling.
- **num.args**: int, required Number of inputs to be upsampled. For nearest neighbor upsampling, this can be 1-N; the size of output will be(scale*h_0, scale*w_0) and all other inputs will be upsampled to the same size. For bilinear upsampling this must be 2; 1 input and 1 weight.
- **workspace**: long (non-negative), optional, default=512 Tmp workspace for deconvolution (MB)
- **name**: string, optional Name of the resulting symbol.

### Details

- **Nearest Neighbor - Bilinear**
  **Nearest Neighbor Upsampling**
  Input data is expected to be NCHW.
  Example::
  
  \[
  x = [[[1. 1. 1.],[1. 1. 1.],[1. 1. 1.]]]
  \]
  
  \[
  \text{UpSampling}(x, \text{scale}=2, \text{sample.type}='\text{nearest'}) = [[[1. 1. 1. 1. 1. 1. 1. 1.],[1. 1. 1. 1. 1. 1. 1. 1.],[1. 1. 1. 1. 1. 1. 1. 1.],[1. 1. 1. 1. 1. 1. 1. 1.],[1. 1. 1. 1. 1. 1. 1. 1.],[1. 1. 1. 1. 1. 1. 1. 1.],[1. 1. 1. 1. 1. 1. 1. 1.],[1. 1. 1. 1. 1. 1. 1. 1.],[1. 1. 1. 1. 1. 1. 1. 1.],[1. 1. 1. 1. 1. 1. 1. 1.]]]
  \]

  **Bilinear Upsampling**
  Uses 'deconvolution' algorithm under the hood. You need provide both input data and the kernel. Input data is expected to be NCHW.
  'num_filter' is expected to be same as the number of channels.
  Example::
  
  \[
  x = [[[1. 1. 1.],[1. 1. 1.],[1. 1. 1.]]]
  \]
  
  \[
  w = [[[1. 1. 1. 1.],[1. 1. 1. 1.],[1. 1. 1. 1.],[1. 1. 1. 1.]]]
  \]
  
  \[
  \text{UpSampling}(x, w, \text{scale}=2, \text{sample.type}='\text{bilinear}', \text{num.filter}=1) = [[[1. 2. 2. 2. 1.],[2. 4. 4. 4. 2.],[2. 4. 4. 4. 2.],[2. 4. 4. 4. 2.],[2. 4. 4. 4. 2.],[2. 4. 4. 4. 2.],[2. 4. 4. 4. 2.],[2. 4. 4. 4. 2.],[1. 2. 2. 2. 1.]]]
  \]

  Defined in src/operator/nn/upsampling.cc:L173

### Value

out The result mx.symbol
mx.symbol.Variable

Create a symbolic variable with specified name.

**Arguments**

- **name**: string The name of the result symbol.

**Value**

The result symbol

mx.symbol.where

where:Return the elements, either from x or y, depending on the condition.

**Description**

Given three ndarrays, condition, x, and y, return an ndarray with the elements from x or y, depending on the elements from condition are true or false. x and y must have the same shape. If condition has the same shape as x, each element in the output array is from x if the corresponding element in the condition is true, and from y if false.

**Usage**

mx.symbol.where(...)

**Arguments**

- **condition**: NDArray-or-Symbol condition array
- **x**: NDArray-or-Symbol
- **y**: NDArray-or-Symbol
- **name**: string, optional Name of the resulting symbol.
mx.symbol.zeros_like

Details

If condition does not have the same shape as x, it must be a 1D array whose size is the same as x’s first dimension size. Each row of the output array is from x’s row if the corresponding element from condition is true, and from y’s row if false.

Note that all non-zero values are interpreted as “True” in condition.

Examples::

x = [[1, 2], [3, 4]]
y = [[5, 6], [7, 8]]
cond = [[0, 1], [-1, 0]]
where(cond, x, y) = [[5, 2], [3, 8]]
csr_cond = cast_storage(cond, 'csr')
where(csr_cond, x, y) = [[5, 2], [3, 8]]

Defined in src/operator/tensor/control_flow_op.cc:L57

Value

out The result mx.symbol

mx.symbol.zeros_like

zeros_like:Return an array of zeros with the same shape, type and storage type as the input array.

Description

The storage type of “zeros_like” output depends on the storage type of the input

Usage

mx.symbol.zeros_like(...)

Arguments

data NDArray-or-Symbol The input

name string, optional Name of the resulting symbol.

Details

- zeros_like(row_sparse) = row_sparse - zeros_like(csr) = csr - zeros_like(default) = default

Examples::

x = [[1., 1., 1.], [1., 1., 1.]]
zeros_like(x) = [[0., 0., 0.], [0., 0., 0.]]

Value

out The result mx.symbol
`mx.unserialize` *Unserialize MXNet model from RObject.*

**Description**
Unserialize MXNet model from RObject.

**Usage**
```r
mx.unserialize(model)
```

**Arguments**
- `model` The mxnet model loaded from RData files.

---

`mxnet` *MXNet: Flexible and Efficient GPU computing and Deep Learning.*

**Description**
MXNet is a flexible and efficient GPU computing and deep learning framework.

**Details**
- It enables you to write seamless tensor/matrix computation with multiple GPUs in R.
- It also enables you to construct and customize the state-of-art deep learning models in R, and apply them to tasks such as image classification and data science challenges.

---

`mxnet.export` *Internal function to generate mxnet_generated.R Users do not need to call this function.*

**Description**
Internal function to generate mxnet_generated.R Users do not need to call this function.

**Usage**
```r
mxnet.export(path)
```

**Arguments**
- `path` The path to the root of the package.
Ops.MXNDArray

Description

Binary operator overloading of mx.ndarray

Usage

## S3 method for class 'MXNDArray'
Ops(e1, e2)

Arguments

e1 The second operand

outputs

Get the outputs of a symbol.

Description

Get the outputs of a symbol.

Usage

outputs(x)

Arguments

x The input symbol

predict.MXFeedForwardModel

Predict the outputs given a model and dataset.

Description

Predict the outputs given a model and dataset.
Usage

```r
## S3 method for class 'MXFeed ForwardModel'
predict(
  model,
  X,
  ctx = NULL,
  array.batch.size = 128,
  array.layout = "auto",
  allow.extra.params = FALSE
)
```

Arguments

- `model`: The MXNet Model.
- `X`: The dataset to predict.
- `ctx`: `mx.cpu()` or `mx.gpu()`. The device used to generate the prediction.
- `array.batch.size`: The batch size used in batching. Only used when `X` is R’s array.
- `array.layout`: can be "auto", "colmajor", "rowmajor", (default=auto) The layout of array. "rowmajor" is only supported for two dimensional array. For matrix, "rowmajor" means `dim(X) = c(nexample, nfeatures)`, "colmajor" means `dim(X) = c(nfeatures, nexample)` "auto" will auto detect the layout by match the feature size, and will report error when `X` is a square matrix to ask user to explicitly specify layout.
- `allow.extra.params`: Whether allow extra parameters that are not needed by symbol. If this is TRUE, no error will be thrown when arg_params or aux_params contain extra parameters that is not needed by the executor.

Description

`print.MXNDArray` print operator overload of `mx.ndarray`
rnn.graph

Generate a RNN symbolic model - requires CUDA

Description

Generate a RNN symbolic model - requires CUDA

Usage

rnn.graph(
    num_rnn_layer,
    input_size = NULL,
    num_embed = NULL,
    num_hidden,
    num_decode,
    dropout = 0,
    ignore_label = -1,
    bidirectional = F,
    loss_output = NULL,
    config,
    cell_type,
    masking = F,
    output_last_state = F,
    rnn.state = NULL,
    rnn.state.cell = NULL,
    prefix = ""
)

Arguments

num_rnn_layer int, number of stacked layers
input_size int, number of levels in the data - only used for embedding
num_embed int, default = NULL - no embedding. Dimension of the embedding vectors
num_hidden int, size of the state in each RNN layer
num_decode int, number of output variables in the decoding layer
dropout
config Either seq-to-one or one-to-one
cell_type Type of RNN cell: either gru or lstm
rnn.graph.unroll  

Unroll representation of RNN running on non CUDA device

Description

Unroll representation of RNN running on non CUDA device

Usage

rnn.graph.unroll(
    num_rnn_layer,
    seq_len,
    input_size = NULL,
    num_embed = NULL,
    num_hidden,
    num_decode,
    dropout = 0,
    ignore_label = -1,
    loss_output = NULL,
    init.state = NULL,
    config,
    cell_type = "lstm",
    masking = F,
    output_last_state = F,
    prefix = "]",
    data_name = "data",
    label_name = "label"
)

Arguments

num_rnn_layer  int, number of stacked layers
seq_len  int, number of time steps to unroll
input_size  int, number of levels in the data - only used for embedding
num_embed  int, default = NULL - no embedding. Dimension of the embedding vectors
num_hidden  int, size of the state in each RNN layer
num_decode  int, number of output variables in the decoding layer
dropout
config  Either seq-to-one or one-to-one
cell_type  Type of RNN cell: either gru or lstm
